AN

ESSAY

ONTHE

WEATHER;

WITH

REMARKS

ON

THE SHEPHERD OF BANBURY'S RULES FOR JUDGING OF IT'S CHANGES;

AND

Directions for preserving Lives and Buildings from the fatal Effects of Lightening.

INTENDED CHIEFLY FOR THE

USE OF HUSBANDMEN.

BY JOHN MILLS, ESQ. F.R.S.

Honorary Member of the Dublin Society, of the Royal Societies of Agriculture of Paris and Rouen, of the Oeconomical Society of Berne, and of the Palatine Academy of Sciences and Belles-Lettres,

THE SECOND EDITION, IMPROVED.

LONDON:

PRINTED FOR S. HOOPER, LUDGATE-STREET.
M DCC LXXIII.

THE REVEREND

GEORGE TILSON, A. M. OF RICHMOND, INSURRY,

A GENTLEMAN SKILLED IN
BOTANY,

A LOVER AND JUDICIOUS ENCOURAGER OF

AGRICULTURE,

AND A DISTINGUISHED FRIEND TO THE LAUDABLE PURSUITS OF ALL MANKIND;

THIS SECOND EDITION OF THE FOLLOWING ESSAY

IS RESPECTFULLY INSCRIBED,

BY

HIS MUCH OBLIGED, AND

MOST OBEDIENT SERVANT,

London, October 12, 1972.

JOHN MILLS.

In one volume 8vo. price bound 5s. fewed 4s.

ESSAYS

MORAL, PHILOSOPHICAL,

AND

POLITICAL,

On the following Subjects;

VIZ.

- I. ON PHILOSOPHY AND PHILOSO-PHERS.
- II. On Projects.
- III. ON LOVE AND JEALOUSY.
- IV. ON COMMERCE AND LUXURY.
- V. ON AGRICULTURE.

By the AUTHOR of this ESSAY.

N. B. The Authors of the Critical Review for January, 1772, conclude their Account of this Work, as follows: viz. "We may fay with Justice of the Whole, that they discover the Author to be a Person of Learning, Taste, and Philosophical Sentiment; and the Third Essay is particularly ingenious, and contains many just observations on Modern Manners.

PREFACE.

HINKING it would be wrong in me to be the first publisher of another person's discoveries, especially when there was reason to presume that the discoverer himself might be induced to communicate them to the public; this essay has lain by for some years, in expectation that my highly respected friend, Dr. Benjamin Franklin, would one day favour the world with what he had before imparted to me concerning the affinity between lightening and the electrical fire, and the means of preserving houses from the dangers of the former. That scruple being now removed, by the Doctor's late publication of his "Experiments and Observations on Electricity," with the addition of his "Letters and 66 Papers on various philosophical sub-" jects," I at length give the following sheets (originally intended as a part of my Treatise on Husbandry) in hopes that they may be of some service to that essentially necessary, but too much neglected class of mankind, husbandmen.

The advantages which may arise from a fore-knowledge of the changes of the weather are so frequently pointed out in the following sheets, that I cannot well do more here, than repeat my advice to farmers, to turn their attention to obfervations of this kind more than they have generally done, with a probable expectation of their reaping a crop of useful knowledge: for though ill-founded predictions have cast a discredit upon the study of, or attention to, the changes of the weather; yet it is hard to fay to what degree of perfection men who make the works of nature their study may arrive, both in tracing the causes of the alterations of the weather, and in fore-feeing the fuccessions of it's changes. --- The fisherman, who has been long practifed in his bufiness, seldom unfurls his fails when a storm is near, owing to his constant observation of the sky: and were farmers equally attentive, and had once acquired as

much judgment in this matter, they would be as feldom overtaken by un-

looked for changes.

They must not however at all times look so high, as to neglect what passes around them on the surface of the earth. The beginning vegetation of plants, especially of the natives of each country, is a kalendar well worthy observation, as a directory of the seasons proper for certain works in the spring: nor should the accidents which happen to even the least useful plants be neglected, because they may afford hints of what should be done to prevent the like evils in plants of greater utility.

Linnæus and his disciples have given excellent instructions on this head. One of them in particular, Mr. Harold Barck, in his very ingenious Dissertation on the Foliation of Trees, presented in 1753 to that great, and hitherto unrivalled school of natural history, the university of Upsal, under the presidence of the excellent Linnæus, tells us it was then the fourth year since that illustrious botanist exhorted his countrymen to observe with all care and diligence, at

what time each tree expands it's buds, and unfolds it's leaves; imagining, and not without good reason, that his country, and the same is equally applicable to every other, would, some time or other, reap some new, and perhaps unexpected benefit, from observations of this kind made in different places.

As one of the apparent advantages, he advises the prudent husbandman to watch with the greatest care the proper time for sowing; because this, with the divine affistance, produces plenty of provision, and lays the foundation of the public welfare of the state, and of the private happiness of the people. The ignorant farmer, continues he, tenacious of the ways and customs of his ancestors, fixes his sowing-season generally to a month, and sometimes to a particular day, without confidering whether the earth be prepared to receive the feed: from whence it frequently happens, that the fields do not return what might be expected, and that what the fower fows with fweat, the reaper reaps with forrow. The wife œconomist should therefore fix certain signs

whereby to judge of the proper time for fowing. We look up to the stars, and, without reason, suppose that the changes on earth will answer to the heavenly bodies; entirely neglecting the things which grow around us. We fee trees open their buds, and expand their leaves; from whence we conclude that spring approaches, and experience supports us in the conclusion: but no body has yet been able to shew what trees Providence intended should be our kalendar, fo that we might know on what day the countryman ought to fow his grain. No one can deny but that the same power which brings forth the leaves of trees, will also make the grain vegetate; nor can any one justly affert that a premature fowing will always, and every where, accelerate a ripe harvest. Perhaps therefore we cannot promise ourselves a happy success by any means fo likely, as by taking our rule for fowing from the leafing of trees. We must, for this end, observe in what order every tree puts forth it's leaves, according to it's species, the heat of the atmosphere, and the quality of the

foil. Afterwards, by comparing together the observations of several years, it will not be difficult to determine, from the foliation of trees, if not certainly, at least probably, the time when annual plants ought to be fown. It will be necessary likewise to remark what sowings made in different parts of the spring produce the best crops, in order that by comparing these with the leafing of trees, it may appear which is the most proper time for fowing: nor will it be amiss in like manner to note at what times certain plants, especially the most remarkable in every province or country, blow; that it may be known whether the year makes a quicker or flower progress.

Linnæus's methods of carefully obbserving the foliation of trees, &c. would undoubtedly determine right the proper time for spring-sowing; and Pliny, after mentioning the several constellations by which sarmers were guided in his time, instructs the husbandman with regard to autumnal sowing, upon a principle similar to that of our great modern naturalist. "Why,

" fays he, (Lib. xviii. c. 25.) does the " husbandman look up to the stars, of which he is ignorant, whilst every hedge and tree point out the feafon by the fall of their leaves? This 66 circumstance will indicate the temperature of the air in every climate, and shew whether the season be early 66 or late. This constitutes an univerfal rule for the whole world; because trees shed their leaves in every country according to the difference of the seasons. This gives a general fignal for fowing; Nature declaring that she has then covered the earth against " the inclemency of the winter, and " enriched it with this manure."

Mr. Stillingfleet, who has given us a judicious translation of several excellent pieces published by sundry disciples of the Linnæan school, informs us, that he himself was told by a common husbandmen in Norfolk, that when the oak catkins begin to shed their seed, it is a proper time to sow barley: "And why," adds he, very properly, "may not some other trees serve to direct the farmer for the sowing of other

" seeds? The prudent gardener never " ventures to put his house plants out " till the mulberry leaf is of a certain " growth." Hesiod, continues this gentleman, (Miscellaneous Tracts, p. 147,) began to fix the proper seasons for plowing, fowing, &c. by the appearance of birds of passage, or of infects, or by the flowering of plants: but we have no record of observations of this kind being made till Linnæus wrote. Hefiod fays, that when the voice of the crane is heard over-head, then is the time for plowing; that if it should happen to rain three days together when the cuckow fings, late fowing will then be as good as early fowing; that when snails begin to creep out of their holes, and climb up plants, it is time to cease digging about the vine.

There is a wonderful co-incidence, which probably takes place in all countries, between vegetation and the arrival of certain birds of passage. Linnæus fays, that the wood-anemone (in Sweden) blows from the time of the arrival of the swallow; and Mr. Stillingfleet finds by a diary which he kept in Norfolk for the year 1755, that the swallow appeared there on the 6th of April, and the wood-anemone was in bloom on the 10th of the same month. Linnæus observes, that the Marsh-marigold blows when the cuckow sings; and Mr. Stillingsleet finds by his diary that the Marsh-marigold was in blossom on the 7th of April, and the cuckow

fung the same day.

The methods here hinted at deserve the most serious attention of every lover of his country. A feries of observations of these kinds, properly made by intelligent persons, in different parts, and afterward rightly compared and combined, would foon afford almost infallible rules to guide the husbandman in one of the most important parts of agriculture. I cannot too strongly recommend it to the public spirited inhabitants of the British dominions in particular, as a means by which the power and opulence of this happy state cannot fail to be considerably increased, and the felicity of individuals to be confequently confirmed.

The principal points necessary in the making of these observations are, 1st, That they be continued for a due length of time, and the time and place of obfervation be particularly specified. 2dly, That they be made on the same subjects: and 3dly, That the soil and exposition be carefully noticed and described, in order to their being duly compared with the field intended to be fown. The necesfity of being as exact as possible in this last article, will appear to every one who does but confider, what all know, that the north-wind, shade, and a moist soil, hinder the leafing of trees, as much as a dry situation on the slope of a hill inclining to the foutb promotes it .---Another circumstance which would greatly facilitate the application of these observations, is, to take the trees in their progressive order of leasing: for nature is always regular, and the guide would then be fure.

The changes of the weather, and their effects on both the animal and the vegetable kingdom, are likewise an object which has been long pursued by the Royal Academy of Sciences, and

especially of late years by the justly celebrated M. Duhamel, in his meteorological observations published annually

in the Memoirs of that Academy.

The different societies of agriculture instituted in the several foreign nations of Europe, have also taken up this subject: that of Berne in particular has likewise published annually observations of this kind: I shall here subjoin by way of appendix, an abstract of those of the year 1766, as a model worthy of imitation. In this abstract, I say but little of the weather in Swisserland, because the Berne journal of the barometer and thermometer would swell this work too much, and might be thought rather too local; though the reader would be furprized to fee the fimilarity in the motion of the barometer in that country and in this.

AN

E S S A Y

ONTHE

WEATHER.

INTRODUCTION.

The industrious farmer from a foreknowledge of the changes of the weather, and the example set us by all the antient writers on husbandry, are sufficient inducements for my endeavouring to draw the attention of husbandmen to observations which must be so highly beneficial to them. It might indeed have been expected, that, considering the great improvements which have been made in natural philosophy in the two last centuries, an accurate account of the weather would ere now have been attained: yet the earliest authors who have treated of husbandry, seem to have established more certain prognostics of the weather peculiar to their climates, than any have done for our's; though it may be prefumed that the operations of nature are fet in a much clearer light to us, than they could be to them, by means of the many and great discoveries which the moderns have made. Perhaps philofophers have not had opportunities, from their own observations, of laying down any certain rules of the changes of the weather, and either despised or neglected the remarks of illiterate country people. Such, it is supposed, was the shepherd of Banbury, whose rules to judge of the changes of the weather are the only observations of this kind that have been adapted to this country; the modern writers on husbandry, who have faid any thing of the weather, and even that great restorer of natural knowledge, lord Bacon, having too fervilely followed the antients.

Who the shepherd of Banbury was, we know not; nor indeed have we any proof that the rules called his were penned by a real shepherd: both these points are how-

ever immaterial: their truth is their best voucher. Mr. Claridge, who published them in the year 1744, fince which time they are become very scarce, having long been out of print, tells us, that they are grounded on forty years experience, and thus, very rightly, accounts for the prefumption in their favour. "The shepherd, whose " fole business is to observe what has a re-" ference to the flock under his care, who " spends all his days, and many of his nights in the open air, under the wide-spread ca-" nopy of heaven, is obliged to take parc ticular notice of the alterations of the weather; and when he comes to take a 66 pleasure in making such observations, it is amazing how great a progress he makes in them, and to how great a certainty he arrives at last, by mere dint of comparing figns and events, and correcting one remark by another. Every thing, in time, 66 becomes to him a fort of weather-gage. "The fun, the moon, the stars, the clouds, "the winds, the mists, the trees, the flowers, "the herbs, and almost every animal with "which he is acquainted, all these become, to such a person, instruments of real know- ledge."

I shall occasionally quote such of the shepherd's rules as may tend to strengthen or confirm my reasonings, by facts; and endeavour to explain others of them on the principles of the latest discoveries, which Mr. Claridge was either unacquainted with, or neglected to notice,

But before I begin to speak of the particular prognostics of the weather, and, with them, of the shepherd's rules, it may not be amiss to give a concise and general account of the following articles, thereby to throw the greater light on the rules themselves, as well as on my observations.

SECT

SECTION I.

Of Clouds, Fog, Rain, Snow, Hail, Thunder and Lightening.

HE higher water is raised in the air, the farther it's parts recede from one another. In this case, they will not probably constitute water, but the primary particles or principles of water. When these particles are equally dispersed in the atmosphere, it is transparent: but when they descend again from the upper regions, and occupy smaller spaces, they associate together, or form a moift vapour, and become clouds. The higher therefore water ascends in the air, the more ferene and dry the weather will be, and the more free from clouds. The atmosphere is usually heaviest at this time; so that, in reality, as observed by Boerhaave, there is then more water in the atmosphere, than when, by reason of the dryness below, people generally imagine there is least in it. The snow seen on the tops of the highest mountains, shews to how great an height water rifes in the atmosphere,

The following feem to be some of the chief causes of the ascent of water and other exhalations into the air.

First; Fire, whether culinary, subterraneous, or of the sun. The subterraneous heat probably arises from the effervescence of different substances under ground, and sometimes from their taking fire. Heat, from whatever cause it arises, renders many particles of water lighter than the lower air; they therefore ascend till they come to air of the same specific gravity, as is justly observed by M. de la Hire, in the Memoirs of the royal Academy of Sciences, for the year 1719.

Secondly; Great quantities of vapours rife from fluids whose particles are put in a violent motion by any cause; as appears from the cloud constantly observed where there is a great fall of water.

The third, and feemingly the most general cause of the ascent of vapours into the atmosphere, is that power which the air has of attracting water, the particles of which being once separated from the mass, ascend

with the air. Hence perhaps it is, that winds carry off great quantities of watery vapours, by bringing a greater number of particles of air into contact with the water. The air feems to have this effect independent of heat; for we find that in the severest winters, a great quantity of fnow, and even of folid ice, evaporates into the air. This power is exerted very differently, according to the weight of the atmosphere. When it is heavy, and the quickfilver in the barometer rifes high, then a great deal of water is taken up by the air but when the quickfilver falls, or the atmosphere becomes lighter, then the air drops the watery vapour, in the form of dew, mist, rain, &c. Hence the use of the barometer, because it gives warning of these changes in the atmosphere, before their effects are either seen or felt by us. And hence we may account for an observation of Pliny's, that the speedy drying of the surface of the earth is a fign of a northerly wind and fair weather; and it's becoming moist, of southerly wind and rain. As the atmosphere approaches to it's greatest height, or the quickfilver rifes high in the barometer, the air takes up all the waste water on the surface of the earth, and so dries it. Hence the farmer may be instructed, never to trust a sun-shining day, while the surface of the earth continues wet; and to rely on a change to dry weather, as soon as he observes the moisture dried up, even though the appearance of the clouds should not be favourable.

This opinion is thus confirmed in the meteorological observations of the Academy of Sciences for the year 1742.

Since water imbibes and absorbs the air that touches it's surface, lodges it in it's interstices, making no longer but one body together; carries it along by it's motion of fluidity to the bottom of the vessel that contains it; and since air, notwithstanding it's specific gravity, which is much less than that of water, unites itself with it; it follows necessarily, that air may take up, absorb, and imbibe water on which it floats, and against which it is continually urged by the whole weight of the atmosphere; and that water, notwithstanding it's greater specific gravity,

may infinuate itself into air, unite with it, follow all its motions, and make but an useless effort to fall back again, so long as it continues intimately mixed.

"The air of itself," fays Dr. Halley, c imbibes a certain quantity of watery va-66 pours, and retains them like falt dissol-" ved in water. The air abounding with 66 this water, being carried against the upper of high and cold mountains, the of particles are condensed by the cold, and se fall to the earth, towards the north and east, during the first part of the night, " and towards the fouth and west after mid-" night, as the air becomes colder. The particles there uniting, are converted to a " real fluid, which glides gently down, or " entering into the caverns of the hills, is es gathered as in an alembic, descends into 66 lower places, and breaking out in the " fides of the hills, forms springs.

"This theory of springs is not a bare hy"pothesis, but founded on experience,
"which it was my luck to gain in my abode
at St. Helena, where, in the night time,

"on the tops of the hills, about eight hun"dred yards above the fea, there was so plen"tiful a precipitation of the vapours, that it
"was a great impediment to my celestial
"observations: for in the clear sky, the
dews fell so fast, as to cover my glasses
"each quarter of an hour with little drops;
"fo that I was necessitated to wipe them off
"so often: and the paper on which I wrote
"my observations, would be immediately
"fo wet with dew, that it would not bear
"ink." This account demonstrates how
great a quantity of watery vapour there is in
the upper regions of the air.

The vapours descend in the atmosphere from various causes. Whatever lessens the specific gravity of the air, causes bodies which before were equiponderant with it, to fall lower into spaces where the air is of the same specific gravity with them; or to fall out of it; as is seen in the receiver of an air-pump, upon drawing out some of the air. When vapours greatly raristed by heat, afterwards cool, and so become specifically heavier; or when any other propelling cause

When several particles meeting together unite, whether by winds blowing from different quarters, or any other cause that creates an unequal motion in the air, whereby the watery particles come into more frequent contact, they become specifically heavier than the air, and therefore descend.

Clouds are the watery vapours collected together, so as to intercept a good deal of light, and render the air more opake than usual: or clouds are only fog or mist raised higher in the air, and there floating about; as is experienced by travellers, who in croffing mountains covered with fuch clouds, never find them to be fnow, or of any firm confistence, unless the mountains are so high as to reach the frozen region of the air. Clouds generally appear to be whiter than fog, owing to the quantity of light reflected from them as far as the fun shines on them. They rife to very different heights in the atmosphere, according to the specific gravity of the watery particles of which they are composed.

Fez is exhalations either rifing flowly from the earth, or returning very flowly to it. When composed of watery vapours only, as those are which arise at sea, it is neither hurtful, nor stinks; but when of other exhalations, it often carries in them the feeds of many diseases. Fog is mostly seen in the night and morning, especially if the sun, in the day, has heated the earth much, which is again cooled after fun-fet. This happens chiefly in spring and autumn; seldomer in the fummer; because there is less difference between the heat of the day and night in the fummer, than in spring and autumn. Fog fometimes wets like fmall rain, and then it is called mift.

In the summer, when the weather is fair, the heat of the sun penetrates to some depth into the earth, and not only water, but other volatile particles are carried up into the air, by the power of the solar rays, and float in it near the surface of the earth. As long as these exhaltations are kept in agitation by the heat of the sun, so long nothing of them appears to the eye: but soon after the solar

heat begins to remit, the air grows cool, whilst the earth, retaining it's heat much longer than the air, continues to breathe out exhalations: whence, in fome places, arifes a white visible vapour called dew; though in general the vapours remain invitible. This visible vapour appears first in watery or marshy places, whence dispersing itself by degrees, it covers the face of the lower grounds with a cloud in the evening and night. In the morning, it is again dissipated by the heat of the rifing fun. This vapour must be of a very different nature in different places, according to the qualities of the various substances in the places whence it arises. For instance, in dry gravelly grounds of a large extent, the dew is entirely water, and usually invisible: while that which arises from standing waters, morasses, bituminous earths, or places abounding with the exhalations of putrid bodies, must have various fubstances in it, and may often be pernicious to health; and yet may be loaded with many particles fit for the nourishment of vegetables.

An opinion long prevailed, that the dew

which is collected on various parts of plants, was the watery vapour which fell from the air. Many and accurate experiments and observations evince, that the dew on plants is most frequently the sweat of the plants continually escaping through the orifices of their vessels; each plant having a different dew, where these orifices are the most numerous and open. This moisture exhales perpetually from plants, but is dissipated by the winds or heat during the day.

Rain is formed, when the watery particles composing a cloud approach so near to each other, that they unite into drops, which becoming specifically heavier than the air, they fall down, and in their descent light upon others, which increase their bulk to what we find them when they reach the earth. If the cause thus uniting them obtains equally through the cloud, and the vapours gradually unite into small drops very little specifically heavier than the air, they fall down in a missing rain. This may happen when the cause acts first in the lower part of the cloud, and gradually proceeds upwards. If

the cause first takes place in the upper part of the cloud, and proceeds gradually downwards, the fmall drops above falling down through others, unite with them; and this continually increasing, they reach the earth in large drops. In fuch a shower, a person ascending a mountain, will find the drops lesser as he ascends. The largest drops of rain fall in the fummer, owing to the vapours being raifed higher in the atmosphere at that time by the heat of the fun; whereas the force of the winter's fun raising the watery vapour to a less height, the rain falls then in small but numerous drops.

If watery exhalations meet with no cause to condense or dissipate them, they sometimes form a thick heavy dry air, which often lasts for several days, without either sun or rain. "In this case," says Dr. Der-" ham, " I have scarce ever known it to " rain, till it has been first fair, or till the " fun has shone out. When this happens, " the wind is generally in the easterly points; " though I have known the fame to happen 66 be the wind where it will. I have per"ceived fome small drops of rain, hail, and "fnow now and then fallling, before any alteration hath happened in the weather."

The higher the watery vapour is raifed in the air, the more it's particles are dispersed in wider spaces; and they at the same time grow colder: for we constantly find that the heat lessens as we approach the summits of the highest mountains, where, even under the equator, a freezing cold preferves perpetual fnow. There is therefore an orbit in the atmosphere concentrical with the earth, in which the water in the air is always frozen, if it's particles are united together. The height of this orbit varies in the higher latitudes, according to the feafon of the year, or warmth of the weather; as may be plainly discerned in mountainous countries, where the frost and snow descend gradually on the mountains, as the winter approaches. Hence the air and gusts of hurricanes are cold, though in hot countries and feafons, because they come from above. When water ascends to this orbit, it must necessarily be congealed into ice, unless it's particles

THE WEATHER. 17

or elements are so far separated, that they do not touch one another. As soon as, from any cause, these particles descend, or come into contact, they form icy concretions, which should should should be soon the surface of bodies they meet with, produce a fine boar frost: or they may be collected in such quantities as to form clouds, or fall down in snow.

In the fummer, and in warm climates, when the watery particles in this orbit, by their union, become heavier than the air is in the spaces they float in, they must fall downward into spaces more replete with vapour, where they unite with other particles, and fo gradually form larger concretions, which put on the appearance of snow or bail. As they begin to unite, there will appear little clouds in the air, which falling downward with a confiderable velocity, increase very fast in their magnitude, by condenfing more vapour, till a violent storm ensues. It is probable that the hail, which is always formed in the upper and cold regions of the air, as it descends by it's weight

into those that are lower and warmer, is there dissolved by the heat, and produces those great showers of rain which accompany thunder and lightening. If the hail is carried so swiftly through the air, that, by reason of it's quick descent, it cannot be melted, it falls to the earth in icy concretions, which, by their size, weight, and motion, often do great damage. Hail-stones are seldom round or smooth, owing to the unequal accession of matter as they fall; and from their striking against one another, a noise is heard in the air.

Thunder and lightening have been variously accounted for in different ages. Since the invention of gunpowder, they have been generally ascribed to a mixture of nitrous and sulphureous vapours by some means set on fire in the air, and exploding like that powder: but though there is indeed something similar in the slash and noise, the other effects of lightening did not seem satisfactorily accounted for by such a cause.

Modern discoveries in electricity, and particularly those of that most skilful naturalist,

THE WEATHER. 19

Dr. Benj. Franklin, whose soaring genius has realized the fable of Prometheus's bringing fire down from heaven, have furnished us with a better theory, now demonstrated by experiments to be the true one. For the electricians observing, that the appearances and effects of the electric fluid agreed with those of lightening in many particulars; viz. i, in a fudden light given; 2, in the colour of the light; 3, in the crooked direction of the flame passing through the air; 4, in fwiftness of motion; 5, in exploding with a noise or crack; 6, in being capable of subfisting in water or ice, and the lightening often proceeding out of clouds with rain and hail; 7, in rending some bodies; 8, in destroying animals; 9, in melting of metals; 10, in firing inflammable substances; and ir, in affording a fulphureous smell; they fuspected the matter of lightening and the electric fluid to be the fame: and as the electric fluid was found to be eafily attracted by sharp metalline points, an experiment was proposed, to try if by erecting such points on high buildings, any electricity

could be obtained by drawing some of that fluid from the clouds. The experiment was made, and fucceeded. The electric fluid drawn from the clouds, is found to have all the properties of that produced by the electric machine, and no other. Light bodies are attracted and repelled by it; bottles are charged (as the electricians speak) and perfons are shocked with it; in short, it is demonstrated to be specifically the same. And it being among the known properties of the electric fluid, that it is eafily conducted by any metal, and conveyed by metal rods or wires in any direction; and that it will leave other fubstances to pass in metal, and do them no damage so far as it can have metal to pass in; an useful inference has hence been drawn, viz. that buildings may be preferved from the stroke of lightening, by fixing pointed iron rods to the highest parts, with wires from fuch rods down to the ground, to receive and conduct the lightening to the earth.

Tall trees, and lofty buildings, as the towers and spires of churches, become some-

THE WEATHER. 21 times conductors between the clouds and the earth; but not being good ones, that is,

not conveying the fluid freely, they are

often damaged.

Buildings which have their roofs covered with lead, or other metal, and spouts of metal continued from the roof into the ground to carry off the water, are never hurt by lightening, and whenever it falls on such a building, it passes in the metals and not in the walls.

When other buildings happen to be within the striking distance from such clouds, the sluid passes in the walls whether of wood, brick, or stone, quitting the walls only when it can find better conductors near them, as metal rods, bolts, and hinges of windows or doors, gilding on wainscot, or frames of pictures; the silvering on the backs of looking-glasses; the wires of bells; and the bodies of animals, as containing watery sluids. And in passing through the house it follows the direction of these conductors, taking as many in it's way as can assist in it's passage, whether in a strait or crooked line,

leaping from one to the other, if not far distant from each other, only rending the wall in the spaces where these partial good conductors are too distant from each other.

An iron rod being placed on the outfide of a building, and continued from the highest part down into the moist earth, in any direction strait or crooked, following the form of the roof or other parts of the building, will receive the lightening at it's upper end, attracting it so as to prevent it's striking any other part; and, affording it a good conveyance into the earth, will preventit's damaging any part of the building.

A small quantity of metal is found able to conduct a great quantity of this sluid. A wire no bigger than a goose quill, has been known to conduct (with safety to the building as far as the wire was continued) a quantity of lightening that did prodigious damage both above and below it; and probably larger rods are not necessary, though it is common in America to make them of half an inch, some of three quarters, or an inch diameter.

The rod may be fastened to the wall,

chimney, &c. with staples of iron.—The lightening will not leave the rod (a good conductor, to pass into the wall (a bad conductor), through those staples —It would rather, if any where in the wall, pass out of it into the rod, to get more readily by that conductor into the earth.

If the building be very large and extenfive, two or more rods may-be placed at different parts, for greater fecurity.

Small ragged parts of clouds suspended in the air between the great body of clouds and the earth (like leaf gold in electrical experiments), often serve as partial conductors for the lightening, which proceeds from one of them to another, and by their help comes within the striking distance to the earth or a building. It therefore strikes, through those conductors, a building that would otherwise be out of the striking distance.

Long sharp points communicating with the earth, and presented to such parts of clouds, drawing silently from them the sluid they are charged with, they are then attracted to the cloud, and may leave the distance so great as to be beyond the reach of striking.

It is therefore that expert electricians elevate the upper end of the rod fix or eight feet above the highest part of the building, tapering it gradually to a fine sharp point, which is gilt to prevent it's rusting.

Thus the pointed rod either prevents a stroke from the cloud, or, if a stroke is made, conducts it to the earth with safety to the building.

The lower end of the rod should enter the earth so deep as to come at the moist part, perhaps two or three feet; and if bent when under the surface, so as to go in a horizontal line six or eight feet from the wall, and then bent again downwards three or four feet, it will prevent damage to any of the stones of the soundation; especially if it can be made to terminate in a place where there is water.

This has been practifed for some years past in several of our American colonies, where thunder storms are most frequent; and no house so guarded has ever been damaged by lightening.

A person apprehensive of danger from

lightening, happening during the time of thunder to be in a house not so secured, will do well to avoid fitting near the chimney, near a looking glass, or any gilt pictures or wainscot; the safest place is in the middle of the room, (so it be not under a metal lustre fuspended by a chain,) sitting in one chair and laying the feet up in another. It is ftill fafer to bring two or three mattraffes or beds into the middle of the room, and folding them up double, place the chair upon them; for they not being so good conductors as the walls, the lightening will not chuse an interrupted course through the air of the room and the bedding, when it can go through a continued better conductor, the wall. But where it can be had, a hammock or fwinging bed, suspended by filk cords equally distant from the walls on every fide, and from the cieling and floor above and below, affords. the fafest situation a person can have in any room whatever; and what indeed may be deemed quite free from danger of any stroke by lightening.

Whoever would be more fully instructed

in these interesting points, will naturally, and very rightly, consult what Dr. Franklin himfelf has said in his *Philosophical Letters**, and particularly the LIXth.

Subjoined to his Experiments on Electricity, printed in 1769.

SECTION II.

Prognostics of the Weather taken from Vegetables and Animals.

the changes of the weather have very fenfible effects on many animals and vegetables, and especially on the flowers of the latter, which open and expand their leaves as if to welcome the fair weather, and shut them to guard the tender fruit from the impending storms. This is remarkably apparent in the flowers of pimpernel (burnet), which Gerard, for that reason, terms the countryman's weather-glass; in the down of dandelion and other downs; and in the swelling and consequent erectness of the stalks of tresoil, against rain. We do not know that animals have any powers fitting them for this quick fense more than men have; except that their fluids and vessels being constantly in a more equal state, owing to their uniform way of living, causes from without have a proportionally greater, or at least more sensible effect upon them, than on us, whose irregularities and inattention render many things imperceptible to us, which the brute creation are manifestly affected by. Virgil's beautiful description of of this sense in animals, is thus rendered by Mr. Dryden:

Wet weather feldom hurts the most unwise;
So plain the signs, such prophets are the skies:
The wary crane forsees it first, and sails
Above the storm, and leaves the hollow vales:
The cow looks up, and from afar can find
The change of heav'n, and snuffs it in the wind.
The swallow skims the river's wat'ry face,
The frogs renew the croaks of their loquacious race.
The careful ant her secret cell forsakes,
And drags her eggs along the narrow tracks.
Huge slocks of rising rooks forsake their food,
And, crying, seek the shelter of the wood.

Besides, the sev'ral sorts of wat'ry fowls,
That swim the seas or haunt the standing pools,
Then lave their backs with sprinkling dews in vain,
And stem the stream to meet the promis'd rain.
The crow, with clam'rous cries the show'r demands,
And single stalks along the desart sands.

Then, after show'rs, 'tis easy to descry Returning suns, and a forener sky.

Their litter is not toss'd by fows unclean,

And owls, that mark the fetting fun, declare A star-light ev'ning, and a morning fair.

Then, thrice the ravens rend the liquid air,
And croaking notes proclaim the fettled fair:
Then round their airy palaces they fly
To greet the fun; and feiz'd with fecret joy
When storms are over blown, with food repair
To their forsaken nests and callow care.

GEORG. I.

Likewise, against rain, numbers of earth-worms will creep out of the ground, moles cast up more earth than usual, fleas bite more than common, spiders crawl more

abroad, flies become uncommonly troublefome, and bees stir not far from their hives.

On the contrary, fpiders webs in the air, or
on the grass or trees, foretell very fair and
bot weather: so do bees, when they sly far
from their hives, and come late home; and
likewise a more than usual appearance of
glow worms by night. Gnats too are said
to foretell the weather, in that, if they play
up and down in the open air near sun-set,
they presage beat; if in the shade, warm and
mild showers; but if they join in stinging
those that pass by them, cold weather and
much rain may be expected.

Again; larks rising very high and continuing to sing for a long time, and kites slying aloft, are signs of fair and dry weather.

In men; frequently, aches, wounds, and corns are more troublesome, either towards rain, or towards frost.

SECTION III.

Prognostics of the Weather, taken from the Sun, Moon, and Stars.

NOW proceed to the shepherd of Banbury, whose rules to judge of the weather I shall give, and at the same time examine how far they are confirmed by reason and other authorities.

Ist Rule. If the sun rise red and firey— Wind and Rain.

2d Rule. If cloudy, and the clouds foon decrease—Certain fair weather.

The shepherd begins with observations arising from the different appearances of the sun. These rules may be extended to all the heavenly bodies: for as their rays pass through the atmosphere, the vapours in the air have the same effect on each.

The rain-bow shews us that the rays of light admit of different degrees of refraction, and that according to those different degrees of refraction, they appear of different colours. A clear unclouded sky teaches us,

that while the vapours are equally dispersed in the atmosphere, the rays reach us without undergoing a change, or variety of colours. It is known to those conversant in experimental philosophy, that this refraction of the rays of light arises from a difference in the denfity of the medium through which the rays pass. It seems probable, that while the watery vapour in the air is divided into it's minutest particles, it perhaps only reslects the rays of light, but does not refract them till collected into the form of water, as into clouds, rain, &c. When the farmer therefore sees the fun or moon rife or fet red and firey, or fees the clouds and horizon of that colour, he may expect wind and rain, owing to the unequal distribution of the vapours, or to their being already collected into watery globules by some preceding cause. Thus Virgil;

Observe the daily circle of the fun,
And the short year of each revolving moon:
By them thou shalt foresee the following day;
Nor shall a starry night thy hopes betray.
When first the moon appears, if then she shrouds
Her silver crescent, tipp'd with sable clouds;

Conclude she bodes a tempest on the main,
And brews for fields impetuous floods of rain.
Or if her face with firey slushings glow,
Expect the rathing winds aloft to blow.
But four nights old, (for that's the surest sign)
With sharpen'd horns if glorious then she shine;
Next day, nor only that, but all the moon,
Till her revolving race be wholly run,
Are void of tempests both by land and sea.

Above the rest, the sun, who never lyes;
Foretells the change of weather in the skies:
For if he rise unwilling to his race,
Clouds on his brow, and spots upon his face;
Or if through mists he shoots his sullen beams,
Frugal of light, in loose and straggling streams;
Suspect a drissing day with southern rain.

Or if Aurora, with half open'd eyes, And a pale fickly cheek falutes the skies; How shall the vine, with tender leaves defend Her teeming clusters, when the storms descend?

But more than all, the fetting fun survey, When down the steep of heav'n he drives the day: For oft we find him sinishing his race, With various colours erring on his face. In firey red his glowing globe descends,
High winds and surious tempests he portends:
But if his cheeks are swoln with livid blue,
He bodes wet weather by his wat'ry hue:
If dusky spots are vary'd on his brow,
And streak'd with red, a troubled colour show;
That sullen mixture shall at once declare
Winds, rain, and storms, and elemental war.

But if with purple rays he brings the light, And a pure heav'n refigns to quiet night; No rifing winds, or falling florms are nigh.

The circle which frequently appears about the moon, and fometimes about the fun, as also the mock-suns and moons, proceeding from the great quantity of watery vapour loading the lower air, likewise presage rain or wind, and often both.

If, according to the fecond rule, the fun rifes cloudy, and the clouds foon decrease, the vapours are more equally distributed in the atmosphere; which equal distribution is also promoted by the warmth of the rising sun. Hence we may account for an observation adopted into all languages,

The evening red, and the morning grey, is a fign of a fair day.

For if the abundance of vapour denoted by the red evening sky falls down in dew, or is otherwise so equally dispersed in the air, that the morning shall appear grey, we may promise ourselves a fair day, from that equal state of the atmosphere.

If, in the morning, some parts of the sky appear green between the clouds, while the sky is blue above, stormy weather is at hand.

The great lord Bacon gives us the following rules to judge of the enfuing weather from the first appearance of the moon, and it is said that these observations of his have never been known to fail.

- 1st. If the new moon does not appear till the fourth day, it prognosticates a troubled air for the whole month.
- 2d, If the moon, either at her first appearance, or within a few days after, has her lower horn obscured or dusky, or any ways sullied, it denotes foul weather before the full; but if she be discoloured in the middle,

forms are to be expected about the full, or about the wane if her upper horn is affected in like manner.

3d. When the moon, on her fourth day, appears pure and spotless, her horns unblunted, and neither flat nor quite erect, but betwixt both, it promises fair weather for the greatest part of the month.

4th. An erect moon is generally threatning and unfavourable, but particularly denotes wind; though if the appear with short and blunted horns, rain is rather expected.

SECTION IV.

Prognostics of the Weather taken from the Clouds.

THE shepherd's 3d rule. Clouds small and round, like a dappled grey, with a north wind, portend fair weather for two or three days.

4th Rule. Clouds large like rocks,—great showers.

5th Rule. If small clouds increase,—much rain.

6th Rule. If large clouds decrease,—fair weather.

7th Rule. In summer or harvest, when the wind has been south two or three days, and it grows very hot, and you see clouds rise with great white tops like towers, as if one were on the top of another, and joined together with black on the neither side, there will be thunder and rain suddenly.

8th Rule. If two such clouds arise, one on either hand, it is time to make haste to shelter.

The third rule feems contrary to an obfervation mentioned by Mr. Worlidge, viz.
that "in a fair day, if the fky feem to be
dappled with white clouds, (which they
usually term a mackarel fky,) it generally
predicts rain." This is confirmed by a very
ingenious gentleman, who has constantly obferved, that "in dry weather, so soon as
clouds appear at a great height striped like
the feathers in the breast of a hawk, rain may
be expected in a day or so."

Mr. Worlidge proceeds thus. "In a clear evening, certain small black clouds appear-

ing, are undoubted figns of rain to follow; or if black or blue clouds appear near the fun at any time of the day, or near the moon by night, rain usually follows.

- "If small waterish clouds appear on the tops of hills, rain follows; as they observe in Cornwall, that
 - "When Hengston is wrapped with a cloud, a Shower follows soon after.
- "The like they observe of Rosemary-topping, in Yorkshire, and many other places in England.
- "If clouds grow or appear fuddenly, the air otherwise free from clouds, it signifies tempests at hand, especially if they appear to the south or west."

If many clouds, like fleeces of wool, are fcattered from the east, they foretel rain within three days.

When clouds fettle upon the tops of mountains, they indicate bard weather.

When the tops of mountains are clear, it is a fign of fair weather.

The account before given of the nature and cause of clouds, explains sufficiently these rules of the shepherd and Mr. Worlidge. As an illustration of the seventh and eighth rules, I shall give the following supposition from Boerhaave's chemistry.

"If a large white, what may be supposed a frozen cloud, be opposed to the sun, the rays reflected by the fide next the fun must rarefy or heat the air betwixt it and the fun, while at the fame time, allowing that the cloud is not transparent, the cold will be great in the part turned from the fun, and the air so much the denser: whence must arife a violent motion of the cloud, which will be the more rapid, the greater the fun's heat is on one fide, and the keener the cold is on the other fide. If a few such clouds are fo disposed, that their joint effects meet in one place, which may often be the case, it is easy to conceive that a very great heat must suddenly arise in such a place, and the air be as greatly expanded therein. On a change of the fituation of the clouds, and a consequent dissipation of the rays of the sun, the heat ceases, and the cold air, snow, hail, rain, or other fubiliances near at hand, will

rush violently into the spaces so heated; whence most stupendous and destructive effects may be produced. Hence it will not be furprifing, that a small cloud appearing in a clear sky, in a hot climate, still increasing till it reaches the earth, produces those direful effects travellers acquaint us they meet with in certain latitudes: and thus, even in our northern climate, small white clouds are fometimes feen at a good height, especially after a drought or calm, continually increasing, and as they increase, turning less and less white, till at length they burst down in heavy showers, which falling in large drops, shew that they come from a considerable height, and that they had probably been hail. As the air admits of greater rarefaction than water, the watery vapour must consequently precipitate out of the heated rarefied air. From this cause the inequality of rain in fuch showers may proceed."

SECTION V.

Prognostics of the Weather taken from Mist.

INTH Rule. If mist rises in low grounds and soon vanishes,—fair weather.

tops,—rain in a day or two.

rises, near the full moon,—fair weather.

12th Rule. A general mist before the sun rises, if in the new moon,—rain in the old.

13th Rule. A general mist before sun rises, if in the old moon,—rain in the new.

Upon a careful perusal of a register of the weather, kept near Oundle in Northamptonshire for several years, and which will be inserted in these sheets, I do not find that the twelfth and thirteenth rules hold so universally true, as to be established rules to judge of the weather. Though this register bears the marks of judgment and great accuracy, and it's having been sent to the Royal Society gives it a

fufficient fanction for truth; and though these rules appear to me in this light, yet the fact may be as mentioned by the shepherd.

It might be expected, that as the joint attractions of the fun and moon have so apparent and great effects on the tide, the same influence would be manifest on our atmosphere and it's contents. Thus, if the atmofphere is loaded with watery vapours in the second and fourth quarters of the moon, it would feem probable, that as their joint attractions daily coincide more and more till the new and full moon, fo long the vapours would be suspended; but that, as after the change, or full moon, their joint attractions leffen every day till the first and third quarter, these vapours would fall down in rain in those quarters of the moon. This opinion, of the weather's being influenced by the age of the moon, is of very long standing; and perhaps in countries where the causes of the changes of the weather act more uniformly, the case may be so. As far as I can judge from the above-mentioned register, the changes of the weather feem to be influenced

more by the moon's place in the ecliptic, than by her age · yet this is not fo constant as to make it an established rule. The influence which the moon is observed to have on the tide, would naturally lead men to expect her having the same influence on the weather: and when an opinion once obtains, that a change of the weather happens at certain times, the change is expected; and as often as it takes place, the remembrance of it remains; but we foon forget the number of times it fails, unless the mind is assisted by a faithful journal of the weather.

While speaking of mists, I think I ought not to omit the following observation, recorded in the memoirs, &c. of the Berne Society, for the year 1763.

In large forests, where the fun never penetrates, there reigns a constant cold; and that it is which renders the air of Swifferland, for example, particularly sharp, and frequently occasions those heavy showers of hail, and other florms, which the inhabitants of that country fo often experience. Thus, as is remarked by one of their ingenious writers, in the west part of the Pays de Vaud, when they see in the morning a small cloud arise over the woods, even in fine calm weather, when no other cloud appears, it seldom happens but that a storm falls in the evening. They observe, that when a mist arises over a certain very cold sountain in the forest of Gibloux, there will certainly be a storm on the same day.

SECTION VI.

Prognostics of the Weather taken from Rain.

OURTEENTH Rule. Sudden rains never last long: but when the air grows thick by degrees, and the sun, moon, and stars shine dimmer and dimmer, it is likely to rain six bours usually.

15th Rule. If it begins to rain from the fouth, with a high wind, for two or three hours, and the wind falls, but the rain continues, it is likely to rain twelve hours or more; and does usually rain till a strong north wind clears the air. These long rains seldom hold

above twelve bours, or happen above once a year.

two before sun-rising, it is likely to be fair before moon, and to continue so that day: but if the rain begins an hour or two after sun-rising, it is likely to rain all that day, except the rainbow be seen before it rains.

A fudden rarefaction of the lower air, or perhaps more frequently a cold cloud descending from above, or cold wind descending from above and condensing the invisible vapours so as to form a cloud, are the most frequent causes of sudden rain. The rain therefore ceases as soon as an equal temperature is restored to the atmosphere: but if the vapours are collected in the manner described in the latter part of the fourteenth rule, it is no wonder that the rain continues longer.

In the state of the air described in the sifteenth rule, the mercury in the barometer will always be found low, which indicates that the atmosphere is light. The rain therefore continues to fall, till a cooler and denser air from the north enables the atmosphere to support the vapours.

The duration of the rain in an inland country, like Oxfordshire, where the shepherd lived, may not exceed twelve hours; but I doubt this will not hold as a general rule either of it's duration or frequency in all places; for near the sea, rains happen often which last a whole day.

Mr. Worlidge mentions the following figns of rain.

"The audibility of founds are certain prognostics of the temper of the air in a still evening: for if the air be replete with moisture over us, it depresses founds, so that they become audible to a greater distance than when the air is free from such moisture or vapours. From whence you may conclude, that in such nights or other times that you hear sounds of bells, noise of water, beasts, birds, or any other sounds or noises more plainly than at other times, the air is inclinable to rain, which commonly succeeds.

⁶⁶ I have often observed that the finking

of rivers more than usual at such seasons of the year, hath been a certain presage of much rain to follow; and that the continuing fall of rivers after rain, hath been a sure presage of dry weather.

- "If the earth, or any moist or fenny places yield any extraordinary scents or smells, it presageth *rain*.
- "If dews lie long in the morning on the grass, &c. it signifies fair weather: but if they rise or vanish suddenly and early in the morning, it presageth rain.
- "There is a small bird, of the size and near the shape of a marten, that at some times slies very near the water, which is a most sure prognostic of tempestous weather; never appearing but against such weather, as hath been constantly observed by the boatmen in the Severn, and channel between the Isle of Wight and the main land.
- "Ducks and geefe picking their wings, washing themselves much, or cackling much, signifies rain.
- "If after rain comes a cold wind, it fignifies more rain.

The nightly virgin, whilst her wheel she plies,
Foresees the storm impending in the skies,
When sparkling lamps their sputt'ring light advance,
And in their sockets oily bubbles dance.

SECTION VII.

Prognostics of the Weather taken from the Winds.

HEN the atmosphere is of the same weight and density over a considerable extent of the furface of the earth, there a calm will obtain: but if this equipoise is taken off, a stream of air, or wind, is thereby produced, stronger or weaker in proportion to the alteration made in the state of the atmosphere. There are divers causes which make these alterations in the equipoise of the atmosphere; fuch as rarefactions or condenfations in one part more than in another; vapours rising from the earth or sea, pressure of the clouds, &c. I shall not attempt here to enter into a disquisition concerning the causes of winds in general, but refer the curious to lord Bacon, Mr. Bohun, Dr.

Halley, Dr. Franklin, and others who have written more fully on this fubject, and confine myself chiefly to the winds so far as relates to this island.

We may affign three causes of our stated winds in this island. The first of these stated winds is the westerly, which so frequently obtains every where beyond the limits of the trade wind, and has been most judiciously accounted for by Dr. Franklin, in his philosophical works (p. 188, et seq). This general westerly wind is found to blow mostly from the north-west in the Ocean, and where other causes do not intervene. Lord Bacon mentions the other two causes, as having been long observed, viz. that winds blow most frequently from the sea; and next, that where there are high mountains covered with snow, stated winds blow from that quarter at the time the fnow diffolves.

Lord Bacon imputes the frequency of the winds from the sea, to the copious ascent of watery vapour from it; and as signs that such vapours do ascend from it, he observes, that "the sea and lakes sometimes swell

very confiderably, though no winds are found to blow, which," fays he, "it is probable is occasioned by the warm vapour rising out of the earth under the water. At fuch times a kind of murmuring noise is heard, the founding of the shore is heard to a greater distance than usual, and sometimes a froth or watery bubbles are feen on the fea, whilst it is flat and calm. Hence miners foretel storms, by the muddiness of the water, or by the fumes which rife in mines, before any figns appear above ground." Mr. Bohun relates, that, in Cornwall, they have fo fure prognostics of storms at sea, from their mines, that the fishermen never presume to tarry out, when the fignal is given by the eruption of certain meteors, which immediately presage a tempest. In St. Owen's bay, in the isle of Jersey," continues he, " the fea is often strangely disturbed before the western storms, even when the air is very calm; and though no wind be stirring, yet the roaring of the waves may be heard, not only over the whole isle, but into France, about thirty miles distant, which is the certain prognostic of an ensuing tempest."

This agitation of the sea, and noise of the water, may be occasioned by a storm in the Atlantic Ocean, with the wind at west; for as the storm proceeds eastward, the waves raised by it will greatly out-go the wind, and thereby reach the eastern coast some hours before the wind arrives there. It is probable, that if any storms arise from vapours ascending thus from the earth under the sea, they are only such as are very violent: for that power which the air has of taking up water, will supply sufficient to occasion the winds so frequent from the sea, and is perhaps their most general cause.

Wind, as the reverend and ingenious Mr. Borlace very properly remarks*, is air in motion, excited by various causes. The sun, by concurrent circumstances in land, water, and vapour, lightens and disperses the air from one place, and at one time, more than at another. Inflammable exhalations, and

^{*} In his excellent Natural History of Cornwall, p. 8.

other explosions shall warm and thin the air in particular places. A cloud or portion of vapour full of electrical matter, passing over a cloud or region of land more destitute of electrical matter, will shed streams of fire upon the less electric body, and thereby excite violent motions, &c. Now, wherever the air is thrown into a state of rarefaction, there a vacuity is produced, and the adjacent air flows as water to the breach of a dam, and the flood is either violent or not, as the space through which it passes is shaped; lasting as the quantity of sluid set in motion, and as the extent of the vacuity is to be replenished. If the vacuity be spacious, the flow will be plentiful (obstructions in the way being allowed for); if the channel through which the influx runs be long, narrow, and funnel-like, the velocity will be great, and vice versa; but if a large quantity of condensed air chances at this time to press forward towards this large vacuity, the motion of the air will be impetuous, or what we call a florm. If, on the other hand, the rarefactions in particular districts be gentle,

and there is room for denser air to succeed without violence, the motion also is gentle; and where no extraordinary rarefactions are produced, and the vapours are equally dispersed, a calm ensues.

If rarefying vapours assume the shape of an oblate disk, over-spreading as a canopy a wide extent, the weight and continuity of the incumbent air is in this district, for a time, and to a certain degree, suspended; the mercury finks in the barometer, and at the same time the current of the air above this disk shall go one way, towards any vacuity which shall create a fresh tendency, and the under current of air, influenced by another rarefaction, shall go in a different, perhaps opposite direction; there being no communication between the currents above and below the disk of vapours, sufficient to determine them to one point. Thus again, by the fall or even recess of a great body of vapours in one place out of our fight, the air over our heads before condenfed, and keeping the mercury high, extends itself into the vacuity, the wind blows, and the mercury falls

in a ferene sky, to our surprize. By the rifing of a like body of vapours, and accumulating the air of our horizon, the mercury rifes in a cloudy and even rainy sky. When the wind is violent, the perpendicular preffure of the air is much leffened by the velocity of the horizontal motion, and the mercury falls. When the air is fullest of vapours, the mercury falls; the pressure of the atmosphere depending not only on the weight of the fluid, but also on the agility and elaflicity of the column of air which is broken and interrupted by fuch a quantity of moiflure floating between, condensing, and ready to fall. These and many other variations which might be mentioned, are the necessary refults of meteors, vapours, and air intermixed in separate portions, and acting with reciprocal, but, generally, very different powers.

The most common and the most violent winds in France come almost always from the south-west, and they very often bring rain; because there rise more vapours from the sea to load these winds, than those which

54 AN ESSAY ON

blow from the east: and it has been observed that clouds never fail to increase the force of the wind. The reason may be this, that the wind, though in itself moderate, being confined between the clouds and the earth, it's violence must in consequence be augmented.

It has frequently been remarked, that the winds in the upper region of the air, as may be seen by the motion of the clouds, are very different from those near the surface of the earth*.

A fign of a change of weather which feemed new and fingular to Mr. Borlace+, was thus, August 15, 1752, the wind at west north west, the sky cloudy, the mercury moving upward in the barometer, at about six in the evening, there appeared in the north east the frustrum of a rain bow. All the colours were lively and distinct. They call it in Cornwall a weather-dog, or weather's eye, and pronounce it a certain sign of hard rain. The mercury fell fe, and that without rain. The next morning was dry, but

^{*} Memoirs de l'Academie Royale des Sciences, pour l'an 1717.

† Natural History of Cornwall, p. 17.

THE WEATHER. 55

not clear: at about eleven it began to rain gently, and at one a flood of rain came on, which continued all night and till the next morning.

Virgil describes thus the signs of an approaching tempest:

For ere the rifing winds begin to roar,
The working fea advances to the shore;
Soft whispers run along the leafy woods,
And mountains whistle to the murm'ring stoods;
And chaff with eddy winds is whirl'd around,
And dancing leaves are lifted from the ground,
And floating feathers on the waters play.

Our nortberly winds in the beginning of the winter may arise from the weight of the cold northern air overcoming the warmer southern air, which, as the heat lessens, is less loaded with vapours, and therefore more easily gives way to the cold northern and denser air. Hence the frequency of northwest winds at that season.

The most general cause of the easterly winds in the spring and beginning of summer, arises from the melting of the snow on the continent, as observed by lord Bacon. The warmth which constantly obtains in a thaw, raises not only much of the melting snow in the air, but the exhalations which had been so long confined by the frost, rise copiously into the air, and become the cause of our easterity winds, which are observed to blow more or less in proportion to the duration and severity of the winter on the continent.

- "Seas, lakes, and great bodies of water, agitated by the winds, continually change their furfaces, as is justly remarked by Dr. B. Franklin*; the cold furface in winter is turned under, by the rolling of the waves, and a warmer turned up; in summer, the warm is turned under, and colder turned up. Hence the more equal temper of sea-water, and of the air over it. Hence in winter, winds from the sea seem warm, winds from the land cold. In summer the contrary.
- "Therefore it is that the lakes west of Pensylvania, as they are not so much frozen nor so apt to freeze as the earth, rather mo-

derate than increase the coldness of the winter winds in that part of America.

"The air over the sea being warmer, and therefore lighter in winter than the air over the frozen land, may be another cause of the general north-west winds, which blow off to sea at right angles from the North-American coast. The warm light sea air rising, the heavy cold land air pressing into it's place.

"Heavy fluids descending, frequently form eddies, or whirlpools, as is seen in a funnel, where the water acquires a circular motion, receding every way from a center, and leaving a vacuity in the middle, greatest above, and lessening downwards, like a speaking trumpet, it's big end upwards.

"Air descending, or ascending, may form the same kind of eddies, or whirlings, the parts of air acquiring a circular motion, and receding from the middle of the circle by a centrifugal force, and leaving there a vacancy; if descending, greatest above, and lesening downwards; if ascending, greatest below, and lessening upwards; like a speaking trumpet standing with it's big end on the ground.

- "When the air descends with violence in some places, it may rise with equal violence in others, and form both kinds of whirl-winds.
- "The air in it's whirling motion receding every way from the center or axis of the trumpet, leaves there a vacuum, which cannot be filled through the fides: the whirling air, as an arch, preventing: it must then pass in at the open ends.
- "The greatest pressure inwards must be at the lower end, the greatest weight of the surrounding atmosphere being there. The air entering, rises within, and carries up dust, leaves, and even heavier bodies that happen to be in it's way, as the eddy, or whirl, passes over land.
- "If it passes over water, the weight of the furrounding atmosphere forces up the water into the vacuity, part of which, by degrees, joins with the whirling air, and adding weight, and receiving acclerated motion, recedes still farther from the center or axis of the trump, as the pressure lessens; and at last, as the trump widens, is broken

THE WEATHER. 59 into small particles, and so united with air as to be supported by it, and become black clouds at the top of the trump.

"Thus these eddies may be whirlwinds at land, water-spouts at sea. A body of water so raised may be suddenly let fall, when the motion, &c. has not strength to support it, or the whirling arch is broken so as to let in the air: falling in the sea, it is harmless, unless ships happen to be under it. But if in the progressive motion of the whirl, it has moved from the sea, over the land, and there breaks; sudden, violent, and mischievous torrents are the consequences."

Without entering, however, into the causes of the frequent changes of our winds, which philosophers are not yet agreed upon, I shall now proceed to the shepherd's rules relating to the winds.

17th Rule. Observe that in eight years time, there is as much south-west as north east winds, and consequently as many wet years as dry.

18th Rule. When the wind turns to northeast, and it continues there two days without 19th Rule. If it turn again out of the fouth to the north-east with rain, and continues in the north-east two days without rain, and neither turns fouth nor rains the third day, it is likely to continue north-east two or three months.

The wind will finish these turns in three weeks.

20th Rule. After a northerly wind for the most part of two months or more, and then coming south, there are usually three or four fair days at first, and then on the fourth or fifth day comes rain, or else the wind turns north again, and continues dry.

2 Ist Rule. If it returns to the fouth within a day or two without rain, and turns northward with rain, and returns to the fouth in one or two days as before, two or three times together after this fort, then it is like to be in the fouth or fouth-west two or three months together, as it was in the north before.

The winds will finish these turns in a fortnight.

fouthern wind, is like to produce a great drought, if there has been much rain out of the fouth before. The wind usually turns from the north to fouth with a quiet wind without rain; but returns to the north with a strong wind and rain. The strongest winds are when it turns from south to north by west.

When the north wind first clears the air, which is usually once a week, be sure of a fair day or two.

23d Rule. If you fee a cloud rife against the wind, or side wind, when that cloud comes up to you, the wind will blow the same way the cloud came. The same rule holds of a clear place, when all the sky is equally thick, except one clear edge.

After carefully comparing the shepherd's 17th rule with the afore-mentioned journal of the weather, kept at Southwick near Oundle, I am sorry to say that they do not agree. Lest the reader should think that justice is not done to the shepherd in this censure, I shall here

give an abstract of every month during the eleven years that this journal was fent to the Royal Society. It will appear from thence, that the number of days of westerly winds greatly exceeds the number of eafterly, and that during the eleven years, the fum total of the fouth-west doubles the number of the north-east. To put it in the most favourable light, the greatest number of north-east winds in any year is 63 days, viz. in the year 1739; and the least number of south-west is 70 days, viz. in 1729. There is not one instance in the eleven years, where the easterly winds continued two or three months, according to the 19th rule. If we attend to the two great causes of westerly winds, viz. the general north-west trade wind, if I may so call it, and the Atlantic ocean to the fouthwest of us, we may rather wonder what cause can counteract them so frequently as we find the easterly winds do.

RESULT

OFA

JOURNAL of the WEATHER

KEPT AT

SOUTHWICK,

Near Oundle, in Northamptonshire,

From the Year 1729 to the Year 1739, inclusive.

The shepherd's observation of the manner in which the winds settle in the east or southwest, is particularly worthy the farmer's attention, because it will lead him to most useful foreknowledge. It is however proper to observe, that as great part of England is an open country, at least free from high hills, the winds and weather are more regular there, than in mountainous countries, or where the coast is intersected by arms of the sea. The shepherd's remark made in the middle of that delightful plain which constitutes the greatest part of England, will therefore not hold so true in other places differently situated.

When he tells us, that in eight years we have as many wet as dry, he does not ascertain what winds bring rain or fair weather; and, as Mr. Worlidge observes, "that wind which brings rain to one part of the island, may not to another: for on whichever coast the sea is nearest, the wind more frequently brings rain to that place, than to another where the sea is more remote. Therefore," says he, "I desire all such as expect any success to

their observations, that they quadrate the rules to the place where they live, and not trust to the observations of other places."

Southerly and westerly winds prove generally rainy in this island, there being so great an extent of sea to the south-west: yet places far distant from that sea, or which are screened from it by high mountains, have fair weather; as is the case on the north-east coast of Scotland, where the vapours are intercepted by the Grampian hills. The easterly winds, coming to the south part of the island over a narrow tract of sea, are generally fair, except when in winter they bring on that dark, heavy fky, described by Dr. Derham. They are extremely sharp and cold in the winter, coming from a frozen continent; but if inclined to the fouth, are hot and dry in the summer, as coming from the continent then heated by the fun. The eafterly winds croffing a much wider fea in their passage to Scotland, prove generally rainy all along the east of that country; but fair on the west. We may easily conceive that the air, in croffing the German

ocean, may take up water enough to cause this rain, by it's faculty of attracting water, before mentioned.

A wind blowing from the sea is observed to be always moift; cold in fummer, and warm in winter, unless the sea be frozen up: (i. e. the temperature of wind blowing over water, is more equal than that of wind blowing over land:) and winds blowing from large continents are dry, warm in fummer, and cold in winter. If the frost is so great as to freeze the vapour as it rises from the fea, it must feel extremely sharp and cold to our bodies; though by the thermometer the cold may be the fame as in lofty fituations to which fuch heavy vapours feldom ascend in winter. This frozen vapour acting as fo many sharp points, may be easily conceived to produce those mischievous effects on tender vegetables, which I noticed in a former work*, as one of the disadvantages of low fituations.

A remarkable proof of this (as I likewife mentioned in the fame place) occurred on the first settlement of the English in North-

^{*} System of Husbandry, vol. 3, p. 461.

America. They imitated our custom of building in vallies, and near rivers: but experience foon taught them, that fuch places are more subject to the suffocating, sultry heat of the fummer; and, what they little expected, to a greater feverity of frost in the winter, than rifing grounds generally are. I have been informed by one of the most curious and intelligent observers of the laws of nature, that the cold there, in their hardest frosts, is found to be so severe in the vallies, to a certain height, as fometimes to kill every tender vegetable, while those on the higher grounds escape. This generally takes place to a regular, determined height, above which the Americans now build their houses. — If I might offer a conjecture concerning the cause of this, I should fay, that the effect of the cold feems to be limited to the height to which the great moisture of the air rises at that season. In the hard winter of 1739-40 the same happened in this kingdom, when the frost was much less severe in it's effect in the hilly countries, than in the low lands.

Lord Bacon observes, that, " when the wind changes conformable to the motion of the fun, that is from east to south, from fouth to west, &c. it seldom goes back; or if it does, it is only for a short time: but if it moves in a contrary direction, viz. from east to north, from north to west, it generally returns to the former point, at least before it has gone quite through the circle. When winds continue to vary for a few hours, as if it were to try in what point they should fettle, and afterwards begin to blow constant, they continue for many days. If the fouth wind begins to blow for two or three days, the north wind will blow fuddenly after it: but if the north wind blows for the same number of days, the fouth will not rife till after the east has blown a while. Whatever wind begins to blow in the morning, usually continues longer than that which rises in the evening."

Mr. Worlidge observes, that " if the wind be east or north-east in the fore part of the summer, the weather is likely to continue dry: and if westward toward the end of the fummer, then will it also continue dry. If in great rains the winds rise or fall, it signifies that the rain will forthwith cease. If the colours of the rain-bow tend more to red than any other colour, wind follows; if green or blue predominate, then rain."

The most considerable thing with regard to the barometer, which marks the weight of the air, is, as M. de la Hire has observed in the Memoirs of the Royal Academy of Sciences for the year 1704, the changes which happen to it in two or three days, wherein we often see it descend, and rise more than an inch. This shews that there must be great variations in a little time in the height of the atmosphere. "In order to account for these different weights of the air, says he, it does not appear to me probable to suppose, as some philosophers do, different liquids, and of different gravities, on the furface of the earth, which are fometimes carried one way, and fometimes another; for we know by obfervation, that the air is commonly lightest, when most loaded with vapour.

" I think one may very well explain, in

the following manner, all that we observe of the weight of the air or atmosphere, in all it's circumstances. We know, by very exact observations, that the barometer rises in general less high between the tropics than in the northern countries; from whence it may be conjectured, that the figure of the atmosphere is an oblong spheroid, whose axis corresponds with that of the earth. Now, as wherever there is air, there may be winds; if the same wind reigns through the whole mass of air, and comes from the south, it will necessarily lower the height of the atmosphere in those countries; and on the contrary, if it comes from the north, it will raise it. But moreover, as winds from the fouth bring us rain, it will follow, that it should rain when the air will appear lighter: the entire contrary must happen from the opposite quarter.

"This is, in general, what must follow from the foregoing supposition: but if the south wind reigns only near the surface of the earth, and there be a northerly wind in the superior region, it may rain although the air appear very heavy; and by a contrary reason, it may be very fine weather with a northerly wind, and the barometer extremely low; for we can only observe the winds that are near the surface of the earth."

That different winds do rule in the air at the same time, and sometimes entirely opposite ones, is frequently evident from the driving of the clouds in different directions. It may happen that the combat of these different winds may occasion storms and hurricanes, which Virgil alludes to in his description of a storm, when he says,

"South, east, and west with mix'd confusion roar." ÆNEID. B. I.

The same prince of poets has elegantly shewn his skill in philosophy, and at the same time in physic, with regard to the influence of the air on animal bodies, in the following lines; which confirm what was before noticed in Sect. II, and might indeed properly have been added thereto:

- 66 But with the changeful temper of the skies,
- As rains condense, and sun-shine rarefies;
- " So turn the species in their alter'd minds,
- " Compos'd by calms, and discompos'd by winds:

From hence proceeds the bird's harmonious voice,
 From hence the crows exult, and frisking lambs rejoice.

"I am persuaded, says M. de la Hire, *that fair or rainy weather do not depend on the weight or lightness of the air; but that they are occasioned solely by the winds: I do not mean the wind in general, but fuch winds as come from a distance from the north and fouth, and occupy the greatest part of the atmosphere, and not fuch as are produced near the furface of the earth: for the fun raising more vapours in the southern countries than in the northern, the fouthern winds most commonly give more rain than the northern: and as we know by all the obfervations which have been made towards the north, that the atmosphere there is higher than towards the equator, it must happen, that the winds which shall blow from the north will cause the atmosphere to rise in our temperate zone more than usual; and by consequence the mercury will be

^{*} Memoires de l'Açademie Royale des Sciences, pour l'an 1715.

raised by the greater weight of the atmosphere; and the air will become serene by such a wind. The contrary must happen with regard to the winds which shall blow from the south upon these countries.

continues he, * as the greatest we had observed at Paris: not but that the thermometer had in like manner risen to 82 degrees
in the years 1706, 1707 and 1709; but
then it rose to that point only once in each of
these years; whereas in 1718 it rose to that
height four different days, viz. August 11th,
21st, 22d, 23d; and it is that continued
heat, although of the same degree, which
makes us feel it's power. The thermometer
rose at sun-rising to 70 degrees on the 22d.

"Some have imagined + that the greater or less heat, which glows in the same season in different years, may arise from the spots that are observed at the same time in the

[†] Memoires de l'Academie Royale des Sciences, pour l'an 1718.

^{*} Ibid. pour l'an 1719.

fun; and as when that planet is spotted it does not throw forth so great a number of rays to the earth, that the heats must of consequence be less than when it has no fpots. But the experience we have had the two preceding years shews, that this explanation is not fufficient: for during these years, 1718 and 1719, we feldom faw the fun without fpots; and fometimes there were so great a number of them at once, that we counted nine or ten at the same time, the greatest part of which were very large: yet notwithstanding so many spots during these two last years, the heat was remarkably violent, and of long continuance; for in the last of these years it continued from the beginning of June to the middle of September. Thus it appears that the different temperature of the same season in different years, cannot be attributed to the spots of the sun, but may more probably be owing to the different exhalations of the earth, fometimes colder, fometimes hotter, and to the diverfity of winds which rule in the fame feafons, and which have not, fo far as we know at present, any regular periods in our climates."

S E C T I O N VIII.

Prognostics of the Weather taken from the Changes of the Seasons.

S every year, and the various feafons of each year, have a peculiar character by which they may be distinguished, as to heat, cold, drought, rain, &c. and as the quality of the seafons has a most sensible effect on the productions of the earth, it is evident, that it must be of the greatest advantage to the farmer to be able to foresee the nature of the ensuing season, because he can thereby suit the culture of his grounds, and his crops, to the weather expected.

The antients had certainly arrived at a more perfect knowledge in this article, than we are possessed of. They, observing that the weather of each season set in at a stated time, imputed it's quality to the influence of certain stars which happened then to be conspicuous. In after ages, monks and designing priests, desirous to ascribe every merit

to their faints, transferred the supposed influence of the stars to the faints whose commemoration happened near the fame time. The moderns, being fensible that the inconceivable distance of the fixed stars, and the smallness of our nearest planets, must render their influence on our atmosphere of no effect, and having but little faith in faints, have, perhaps injudiciously, rejected the observations of the antients, without confidering, that the facts might have been discovered first, and the stars and faints only called in to account for them. The antients acted more rationally than the monks, in not fixing thefe changes of the weather to particular days, but only to a stated time of the year, as appears from Pliny and other writers on this subject.

By the help of the barometer, we feem to regain that foreknowledge of the weather which still resides in brutes, and which we forseited, both by not continuing in the open air as they generally do, and by our intemperance's lessening our sensibility of external objects.

Authors are generally agreed, that the tiling of the mercury forebodes fair after foul, with eafterly or north-easterly winds; and that it's falling portends southerly or westerly winds, either stormy, or with rain.

The more northerly places experience greater alterations in the barometer, than the more foutherly. Within the tropics, or near them, there is little or no variation in the height of the mercury.

In serene settled weather, the barometer is high. Other things equal, the greatest heights of the mercury are upon easterly and north-easterly winds. During great winds, though unaccompanied with rain, the mercury is lowest of all, especially if the wind be southerly. After great storms of wind, when the mercury has been low, it generally rises again. Other things equal, the mercury is higher in cold weather than in warm, and usually more so in the morning and evening, than at mid-day.

When the character of the season is once ascertained, the returns of rain, or fair weather, may be judged of with some degree of

certainty in some years, though but scarcely to be gueffed at in others, by means of the barometer; for, in general, we may expect, that when the mercury rifes high, a few days of fair weather will follow. If the mercury falls again in two or three days, but foon rifes high, without much rain, we may expect fair weather for several days; and in this case, the clearest days are after the mercury begins to fall. In like manner, if the mercury falls very low, with much rain; rifes foon, but falls again in a day or two, with rain; a continuance of bad weather may be feared. If the fecond fall does not bring much rain, but the mercury rifes gradually pretty high, it prognosticates settled good weather of some continuance. When a heavy rain has fallen upon the mercury's finking, and it's continuing steadily low, the weather is sometimes fair, and promises well; but no prudent man should trust to such appearances. There is indeed a caution of this kind which the poorest may profit by. When the mercury rifes high in the barometer, the air fucks up all the moisture on the surface of the earth,

THE WEATHER. 83

even though the sky be overcast, and that is a sure sign of fair weather: but if the earth continue moist, and water stands in shallow places, no trust should be put in the clearest sky, for in this case it is deceitful.

Towards the end of March, or more generally in the beginning of April, the barometer finks very low, with bad weather; after which, it seldom falls lower than 29° 5'. till the latter end of September or October, when the quickfilver falls again low, with stormy winds, for then the winter constitution of the air takes place: from October to April, the great falls of the barometer are from 29° 5' to 28° 5'; fometimes lower: whereas during the fummer constitution of the air, the quickfilver feldom falls lower than 29° 5'. It therefore follows from hence, that a fall of one tenth of an inch, during the fummer, is as fure an indication of rain, as a fall of between two and three tenths is in the winter.

It must, however, be observed, that these heights of the barometer hold only in places nearly on a level with the sea; for experi-

ments have taught us, that for every eighty feet of nearly perpendicular height that the barometer is placed above the level of the fea, the quickfilver finks one tenth of an inch: now by an accurate comparison between the motion of the barometer in inland and higher places, with it's motion in a place on a level with the fea, the heights of these inland places may be pretty nearly ascertained; and observations must determine the heights of the quickfilver, which in each place denote either fair or foul weather.

In all places nearly on a level with the sea, rain may be expected when the quicksilver falls below thirty inches. This points out one cause of the more frequent rains in lofty situations, than in low open countries. Thus double the quantity of rain falls at Townly-hall in Lancashire, that does at London.

·Very heavy thunder storms happen, without sensibly affecting the barometer; and in this case the storm seldom reaches far. When a thunder storm is attended with a fall of the barometer, it's effect is much more extensive. And here I must mention an observation which has often been verified by a friend of mine who keeps a regular journal of the weather, viz. that when the quickfilver falls very low, and the weather continues mild and the wind moderate, there is at the same time a violent storm in some distant place: this accounts for a falle prognostic, often unjustly laid to the charge of the barometer; and was fignally inftanced in the remarkably great fall of the barometer on the 22d of November last (1768), when the quicksilver fell in the night to nearly 28° 3 inches. The weather here (in London) was then mild, with little rain, and the wind moderate; and accounts have fince been received of a violent storm of wind at the same time in the Atlantic ocean, west of England and Ireland, which extended to the English and St. George's channels.

That valuable friend of mankind, Benjamin Franklin, LL. D. F. R. S, and honorary member of the Royal Academy of Sciences at Paris, whose piercing eye and comprehensive judgment let nothing escape him,

has, in one of his philosophical letters*, by a fingle instance, accounted more rationally for the causes and progress of storms, than all who have gone before him have done; with this farther advantage, that his reasoning is confirmed by observation.

in North-America begin first, in point of time, in the south-west parts: that is to say, the air in Florida and Georgia, the farthest of our colonies to the south-west, begins to move south-westerly before the air of Carolina, which is the next colony north eastward; the air of Carolina has the same motion as the air of Virginia, which is still more north-eastward; and so on north-easterly through Pensilvania, New-York, New-England, &c., quite to Newfoundland.

"These north-east storms are generally very violent, continue sometimes two or three days, and often do considerable damage in the harbours along the coast. They are attended with thick clouds and rain.

^{*} Letter XXXVI.

What first gave me this idea, was the following circumstance. About twenty years ago, a few more or less, I cannot from my memory be certain, we were to have an eclipse of the moon at Philadelphia, on a Friday evening, about nine o'clock. I intended to observe it, but was prevented by a north-east storm, which came on about seven, with thick clouds as usual, that quite obscured the whole hemisphere. Yet when the post brought us the Boston news-paper, giving an account of the effects of the same storm in those parts, I found the beginning of the eclipse had been well observed there, though Boston lies north east of Philadelphia about four hundred miles. This puzzled me, because the storm began with us so soon as to prevent any observation, and being a north-east storm, I imagined it must have begun rather fooner in places farther to the northeastward, than it did at Philadelphia. I therefore mentioned it in a letter to my brother who lived at Boston; and he informed me the storm did not begin with them till near eleven o'clock, fo that they had a good obfervation of the eclipse: and upon comparing all the other accounts I received from the several colonies, of the time of the beginning of the same storm, and since that of other storms of the same kind, I found the beginning to be always later the farther northeastward. I have not my notes with me here in England, and cannot, from memory, say the proportion of time to distance; but I think it is about an hour to every hundred miles.

"From thence I formed an idea of the cause of these storms, which I would explain by a familiar instance or two—Suppose a long canal of water stopped at the end by a gate. The water is quite at rest till the gate is open, then it begins to move out through the gate; the water next the gate is first in motion, and moves towards the gate; the water next to that first water moves next, and so on successively, till the water at the head of the canal is in motion, which is last of all. In this case all the water moves indeed towards the gate, but the successive times of beginning motion are the contrary way, viz.

THE WEATHER. 89

from the gate backwards to the head of the canal.—Again, suppose the air in a chamber at rest, no current through the room till you make a fire in the chimney. Immediately the air in the chimney being rarefied by the fire, rifes; the air next the chimney flows in to fupply it's place, moving towards the chimney; and, in consequence, the rest of the air fuccessively, quite back to the door. Thus, to produce our north-east storms, I suppose some great heat and rarefaction of the air in or about the gulph of Mexico; the air then rifing has it's place supplied by the next more northern, cooler, and therefore denser and heavier air; that, being in motion, is followed by the next more northern air, &c. &c. in a successive current, to which current our coast and inland ridge of mountains give the direction of north-east, as they lie north-east and south-west.

"This I offer only as an hypothesis to account for this particular fact; and, perhaps, on farther examination, a better and truer may be found. I do not suppose all storms generated in the same manner. The north-

west thunder-gusts in America, I know are not."

If accounts from different parts of Europe were compared on the above-mentioned very great fall of the barometer on the 22d of November, 1768, with the same accuracy as was done in America by the judicious Dr. Franklin, the origin and progress of storms which probably accompanied this fall, might be traced. To our woeful experience, we in England long felt the consequences of the effects which attended the subsequent fall of the barometer, from the 30th of November to the 3d of December of the same year, in the deluges of rain which fell almost universally.

Heretofore, the general idea was, that the progress of the storm was to be estimated by the celerity of the wind: and hence a velocity was sometimes assigned to the wind, which perhaps scarcely ever existed; as Dr. Franklin's observations have fully proved.

Certain it is, that the character of the seafon is less steady at the equinoxes, and more regular during the intermediate months. The advocates for the celestial influence on the atmosphere think, that the changes of the weather are in a great measure regulated by the moon's place in the zodiac, or by her situation with respect to the sun: but observation has not yet ascertained any thing on this head.

Whatever the causes of the changes in the weather, or, what is nearly the fame, in the motion of the quickfilver in the barometer, may be, whether celestial or terrestrial, their effects are generally felt over a confiderable extent of country at the same time. Every one may be affured of this, by comparing accounts kept at distant places, of the play of the barometer. They will find, that the great falls or rifes of the mercury happen nearly at the fame time, in almost all the northern countries of Europe; I fay nearly, because a difference will be observed, usually attending the direction of the wind. If these causes were celestial, the effects would be univerfally the same, except where varied by the situations with regard to seas, mountains, &c. As this is not the case, the

causes must probably be sought for in the earth. This opinion is favoured by the obfervations of miners, who have been generally sensible of some prognosticating circumstances in mines, before any change of the weather appeared in the air.

The hurricanes which desolate Saxony are all formed in, or at least all proceed from the mines in the mountains of Freyberg, situated south-west of Dresden and south-east of Leipzig; as is remarked by Count Algarotti, in his 8th letter to Lord Hervey.*

Even the limited fore-knowledge above pointed out would be of great use to the husbandman, if duly attended to; for instance, at the time of hay-making, when it would be of considerable advantage for him to be able to judge whether he may cut his grass with a prospect of fair weather to dry it; and at all times of the year, in order to his getting ready every thing necessary for carrying into execution the works proper for each season.

Besides a barometer, for the purposes

^{*} See Algarotti's Letters upon Russia.

above-mentioned, it is likewise necessary for whoever would keep an exact register of the weather, to be also provided with a thermometer, in order to notice and mark down the changes which happen in the heat or temperature of the air. This is not a matter of curiosity only, but of real utility: for, from the changes in the temperature of the air, which attend every change of weather, some happy genius may possibly discover causes of the alterations in the degrees of heat, which may lead to a more satisfactory account than any we yet have, of the changes of the year.

Every change of the weather is attended with a change in the temperature of the air, which a thermometer placed in the open air, will point out, tometimes before any alteration is perceived in the barometer. This change in the temperature of the air arises from causes yet unknown to us, and of which the discovery should be the object of the curious observer. The early intimations of changes in the weather given to miners, when working deep under ground, makes it probable, that the temperature of the air de-

pends much on what passes beneath the surface of the earth; and this is confirmed by every general thaw, in which the ice is as much melted in the under part (and thereby loosened from the earth,) as it is on the surface. The uncommon degree of heat which sometimes happens in the winter and early in spring, must likewise be occasioned by somewhat proceeding from the earth; as does also, probably, the sultry heat frequent in the summer, and which is generally the fore-runner of thunder.

The knowledge of the exact degree of cold in the winter, is of consequence to the farmer; for it has been observed, that when the frost is so keen as that the thermometer sinks fourteen degrees on Fahrenheit's scale, most succulent vegetables are thereby destroyed, such as almost all the cabbage or kale tribe, turneps, &c. for their juices being then frozen hard, their yessels are thereby torn as a funder or split, so that when the thaw comes on, the whole substance, for instance of turneps and apples, runs into a putrid mass. In this case, the most likely

way to prevent their being lost, or at least to prevent a total loss of them, is to immerse what is so frozen in cold water, till the frost is extracted by the water: the loss is thereby delayed a little, and indeed only delayed; for what is not used very speedily, will soon putrefy, notwithstanding this care. The knowledge of this consequence of so severe a frost, may however put the farmer on some method of repairing the loss he sees coming on. Time may point out other useful observations, which may arise from the knowledge of what may be discovered from the changes in the thermometer.

A strict observer of the weather may also, rightly, wish to keep an account of the degree of moisture of the air, or at least of its sensible variations. There are several means of doing this; for whatever body either swells or shrinks by moisture or dryness, is capable of being formed into an hygrometer: such are most kinds of wood, especially white wood, as poplar, birch, plane, ash; even deal will do. On this principle it is, that wedges of well-dried wood are made use of

to cleave or raise rocks or stones: for as the moisture of dew, rain, or water applied to them, enters into them, they swell and overcome an inconceivable resistance. Ropes or strings made of hemp, slax, or any other vegetable substance, become also hygrometers. This is well known to failors, who, according to the dryness or moisture of the air, find the shrouds of their vessels slack or tightened, so as, in the latter case, to be in danger of breaking. The use that was made of water applied to the tackle employed in raising the samous obelisk at Rome, is well known.

Stretch a cord or fiddle-string, fastened at one end over a pulley, and to the other end tie a weight: this will rise or tall as the air becomes dry or moist, and consequently be an hygrometer.

Animal substances twisted and dried answer the same purposes, as siddlers often find to their cost, when the too great moisture of the air breaks their strings.

A great misfortune attending the use of all these substances is, that by use they become sensibly less and less accurate, so as at length

hot to undergo any visible alteration from the different states of the air, in regard to dryness or moisture. On this account a sponge may be preferred, as being less liable to be so changed. To prepare the sponge, first wash it in water, and when dry, wash it' again in water wherein Sal Ammoniac, or falt of Tartar, has been dissolved; and let it dry again. Now, if the air becomes moift, the sponge will grow heavier; and if dry, it will become lighter.

Oil of vitriol is found to grow fenfibly lighter or heavier in proportion to the leffer or greater quantity of moisture it imbibes from the air. The alteration is fo great, that it has been known to change it's weight from three drams to nine. The other acid oils, or, as they are usually called, spirits, or oil of tartar per deliquium, may be substituted in lieu of the oil of vitriol.

In order to make an hygrometer with these bodies which acquire or lose weight in the air, place fuch a fubstance in a scale on the end of a steel-yard, with a counterpoise which shall keep it in equilibrio in fair weather:

the other end of the steel-yard, rising or falling, and pointing to a graduated index, will shew the changes. Whoever would be more accurately informed, may consult the Philosophical Transactions.

It was observed by the antients, that the early or late arrival of birds of passage indicates the nature of the approaching feafon; whether it will be early or late, fevere or mild. In the fame manner, Linnæus advises hufbandmen to mark the first figns of a beginning vegetation of fuch plants as grow wild, and are natives of the climate; for that they, by their early or late shooting, inform the attentive farmer of the approach of spring. He advises the husbandman to extend these remarks to different plants, whose vegetation has been observed to coincide with the times of fowing particular feeds. These are objects highly worthy of a place in fuch a journal of the weather as there still remains too much room to wish for; because facts of this kind would remain, from year to year, a register of the state of every article any way relative to rural oeconomics: and upon this

principle it is, that M. Duhamel has very judiciously added to his journal of the weather, an account of the state of all the vegetables and animals useful in a farm; or, which is the same, of the effects of the weather on them.

The only method by which the changes of the weather can be traced with precision, undoubtedly is to keep regular registers of the weather, and mark every appearance in the heavens or on the earth, which may tend to point out the approaching seasons. The very business of the farmer necessarily keeping him much in the open air, would render this an easy task to him; and his progress in fixing sacts, and in drawing judicious conclusions from them, would perhaps be much more speedy and successful than he himself might expect.

Having but few rules relative to the Changes of the Seasons, founded on observations, unless the shepherd of Banbury's be reckoned such, I shall endeavour to collect the most rational that I have met with, and accordingly begin with his

24th Rule. If the last eighteen days of Fe-

bruary and the first ten days of March* be for the most part rainy, then the spring and summer quarters will be so too: and I never knew a great drought but it entered in at that season.

25th Rule. If the latter end of Ottober and beginning of November be for the most part warm and rainy, then January and February are like to be frosty and cold, except after a very dry summer.

26th Rule. If October and November be fnow and frost, then January and February are like to be open and mild.

Mr. Claridge gives us the following observations made by our forefathers;

Janiveer freeze the pot by the fire.

If the grass grow in Janiveer,

It grows the worse for't all the year.

The Welchman had rather see his dam on the bier,

Than see a fair Februeer.

March wind and May sun

Makes cloaths white, and maids dun.

When April blows his horn,

It's good both for hay and corn.

^{*} It is to be observed, that the shepherd reckons by the old slile.

An April flood
Carries away the frog and her brood.
A cold May and a windy
Makes a full barn and a findy.
A May flood never did good.
A fwarm of bees in May
Is worth a load of hay.
But a fwarm in July
Is not worth a fly.

The following rules are laid down by Lord Bacon:

If the wainfcot or walls that used to sweat be drier than usual, in the beginning of winter, or the eves of houses drop more slowly than ordinary, it portends a hard and frosty winter: for it shews an inclination in the air to dry weather, which, in winter, is always joined with frost.

Generally, a moist and cool summer portends a hard winter.

A hot and dry summer and autumn, especially if the heat and drought extend far into September, portend an open beginning of winter, and cold to succeed towards the latter part of the winter, and beginning of spring.

A warm and open winter portends a hot and dry fummer; for the vapours disperse into the winter showers: whereas cold and frost keep them in, and convey them to the late spring and following summer.

Birds that change countries at certain seafons, if they come early, shew the temper of the weather, according to the country whence they came: as, in the winter, wood-cocks, fieldsares, snipes, &c. if they come early, shew a cold winter; and the cuckoos, if they come early, shew a hot summer to follow.

A ferene autumn denotes a windy winter; a windy winter, a rainy spring; a rainy spring, a ferene summer; a serene summer, a windy autumn: so that the air, on a balance, is seldom debtor to itself; nor do the seasons succeed each other in the same tenor for two years together.

Mr. Worlidge remarks, that

If at the beginning of the winter the fouthwind blow, and then the north, it is like to be a cold winter: but if the north-wind first blow, and then the fouth, it will be a warm and mild winter.

VIRGIL.

If the oak bear much mast, it foreshews a long and hard winter. The same has been observed of hips and haws.

If broom be full of flowers, it usually signifieth plenty.

Mark well the flow'ring almonds in the wood; If od'rous blooms the bearing branches load, The glebe will answer to the sylvan reign, Great heats will follow, and large crops of grain. But if a wood of leaves o'er shade the tree, Such and so barren will the harvest be. In vain the hind shall vex the threshing floor, For empty chaff and straw will be thy store.

This observation, says Mr. Worlidge, hath proved for the most part true for several years now past; as in 1673 and 1674 there were but sew nuts, and cold wet harvests: in 1675 and 1676, were plenty of nuts, and heavy and dry harvests; but more especially in 1676 was a great shew of nuts, and a very hot and dry harvest succeeded.

The excessive cold of this winter, says M. de la Hire, speaking of that of the year

1709*, in which the thermometer funk to 5 degrees on the 10th of January, came on without any confiderable wind, and what little wind there was, came from the fouth; and when the wind increased and turned to the north, the cold diminished. The mountains of Auvergne, which are to the fouth of Paris, were at that time all covered with fnow.

Another furprising thing was, that notwithflanding the violence of the cold, the river Seine was not entirely frozen over at Paris, but the middle of it's current continued free, except that there floated in it large pieces of ice: yet in less rigorous winters it hath been often so frozen, that carriages could pass over it. The cold of this winter was fo sudden, that the ice at the edges, and in the lesser rivers, was so fast bound at once, that few flakes of it broke off, and they generally fell in the middle of the stream; so that the violence of the frost was in part the cause that the river Seine was not frozen over.

^{*} Memoires de l'Academie Royale des Sciences, pour l'an 1709.

Though the year 1714 was dry, the rain being only 14 inches and 3; yet as there were many thick fogs during the whole of that year, the harvest was very plentiful, and the fruits were extremely well ripened. Fogs are much more ferviceable than rains, for the nourishment of plants.*

Before I conclude, it may not be amiss to observe, how different the weather sometimes is in climates not very distant. In the year 1751, we had a very rainy fummer throughout England, and the barometer was very unsettled. At the same time an extraordinary drought prevailed in Italy. #

At Brest, in the year 1725, the barometer feemed fixed at 26° 4' from the 2d of February to the 1st of September, when it rose fuddenly to 28°. The rains were excessive; a perfect deluge drowned every thing thereabouts. At the same time the weather was, as usual, changeable at Paris.+

APPENDIX.

ABSTRACT

OF THE

METEOROLOGICAL OBSERVATIONS

MADE BY THE

Oeconomical Society of Berne,

For the Year 1766.

A P P E N D I X.

JANUARY.

HIS month was exceedingly cold and dry; the barometer as high as it was ever feen; the wind conftantly N. and N. E. attended with very little fnow. No rain at Berne. Our lakes were frozen so hard, that they bore every kind of carriage without risk, the ice being six inches thick.

The cold penetrated to such a degree, that the wine was frozen in several vaults; and in our fields and vineyards, the earth was frozen three feet deep. Many vines, especially the old ones, and even chesnut trees and oaks, were split by the severity of the frost, particularly on the heights. Where a good deal of snow had fallen, the springs were not frozen; but in other places they were dried up, by which means the water of the river Aar was extraordinary low.

In the beginning of the month, the frost was exceedingly severe; about the middle, it abated; but towards the end, it set in again as hard as at first. The sky was cloudy

TIO APPENDIX.

during the severity of the cold, and there were frequent fogs.

The crops fown in the autumn, especially in moist soils, made a poor appearance. The frost penetrated least deep in the grounds on which scourings of ponds, &c. or marle had been laid; these substances preventing the soil's being frozen so hard as it would otherwise have been.

The pastures which had been watered were one continued sheet of ice, and it was feared they would be greatly damaged by it.

Pleurisies were very frequent during this month. In some places dysenteries began. Some were attacked with apoplexies, violent coughs, rheums, and other disorders of the season. The cattle continued very healthy, except the sheep, many of which were seized with inflammations on the lungs.

FEBRUARY.

HE beginning and end of this month were very cold: the middle of it was fomewhat milder. The frost penetrated so

deep into the houses, that the carrots, potatoes, and other plants of this kind were frozen in most of our cellars, and in holes dug in the earth for sheltering them.

The barometer varied greatly, being fometimes very high, and fometimes very low.

The wind blew mostly from the north, and rarely from S. or W. No rain.

The ground under corn looked like a fallow, the blades being quite yellow. It was not till the end of the month that they began to turn green. The great quantities of fnow deeply frozen in the vallies between the mountains, and in shaded places, threatened much danger to the corn.

The damage done to the vines could not be judged of this month, but it was plain they had suffered very much; for in places where fome began to prune them, their wood was yellow and quite dry. The earth could not yet be opened about them.

Some mild days melted the greatest part of the ice that covered the pastures, and in the places where that happened they appeared pretty green.

Trees suffered exceedingly from the cold, great numbers of them being split. Most of the laurels, sig-trees, and rosemary bushes, perished, and scarce any thing escaped in the gardens.

Notwithstanding the rigour of the weather; storks appeared towards the latter end of the month, but somewhat later than usual.

The bees did not escape the severity of the cold, which killed great numbers of them. They began to go out on the 17th, and their hives were cleaned.

Putrid fevers, pleurisies, rheums, and inflammations in the throat, prevailed. Few children escaped the measles. Many sheep still died.

M A R C H.

HE beginning and end of this month were cold; the latter, especially, was rainy and stormy: the middle of it was pretty mild and agreeable. The snow and ice melted; though it snowed a little towards the end of the month. The lake of Bienne

was so strongly frozen on the first of March, that a carpenter built a spacious booth a confiderable way out upon the ice, and made a very great fire in it. The ice did not become loose on the sides of the lake till the middle of the month, and it continued in one entire piece in the middle till the 23d and 24th.

The wind blew generally from the N. E. and N. W. Rain fell to the depth of ½ an inch.

Contrary to all expectation, the young corn looked well. The light and wet foils only had suffered. Our husbandmen began to sow their spring crops; but the season was so cold and wet, that they were obliged to give it up.

The hurt which the vines had sustained from the frost appeared now more and more: almost all those that were six or seven years old, perished. In general, the vines in the plains and light soils suffered more than those on hanging grounds and strong soils. The vine-yards facing the North suffered least. The vines bearing red grapes perished most. Few were yet laid down, the effects

of so doing being still very uncertain. Towards the end of the month the pruned vines began to weep, and upon cutting them anew, the wound was of the colour of a rotten apple. The buds fell off in powder with the slightest touch.

The pastures remained covered with ice till the middle of the month, when the earth was thawed; but there was yet no verdure even in places free from ice. The first violets were seen on the 8th.

The gardens, in which scarce a plant had escaped the severity of the cold, began to be put in order in the beginning of this month.

The cold nights kept back the bloom of the trees. In the second week the apricots began to blossom; but they suffered much from the cold. Of all the fruit trees, the sign suffered most from the cold. The other trees were full of blossoms. The service trees, which usually blossom in February, were not in bloom this year till the end of this month.

Most of the bees perished; and we were

obliged to feed those that remained, to preferve them from the same fate.

Putrid fevers and pleurisies carried off many people; and the sheep still continued to die.

APRIL.

THE weather was dry and fine during this month, though the nights were a little cold, with a few hoar-frosts. There was frequent thunder, accompanied with cold rains. The N. and N. E. winds prevailed most.

The barometer varied but little.

The winter corn in general looked well, and the spring corn came up very well every where, the feafon being very favourable.

The pastures did not recover their verdure till the end of the month. The frost had destroyed the turf in many places. Towards the end of the month, dews and mild rains brought the grass on very quick.

This month shewed us how much the

vines had fuffered. Half of them had perished; in some places scarce one remained out of forty; and what rendered this loss the more grievous, was, that the best were those which suffered most. Those which were not destroyed, began to bud about the middle of this month; and the roots of those whose branches had been killed made shoots, from which, however, no fruit could be expected, till after they should be pruned and laid down. The vines were dug round from the beginning of this month.

The feeds fown in gardens rose but slowly, owing to cold winds; and flowers also felt the unkindly feafon.

The trees blossomed furprizingly well. The almonds were in bloom on the 12th. The walnut-trees promifed well. The cherries were in bloom by the 21st, and made a promifing appearance. Not so the apples, and still less the apricots and peaches.

Some hives of bees were preferved by dint of care, and by feeding them.

The nightingale was heard on the 4th.

and the cuckow the next day. The swallow appeared at the same time.

The feafon still continued fickly, though few died. All creatures were healthy, excepting that some dogs ran mad.

MAY.

ROM the beginning to the end of this month the weather was cold and rainy, with frequent hail. The depth of rain that fell here (at Berne) was 6 inches 3/4.

The winter corn was thin and stinted, owing to the cold and wetness of the season; though in some places it had a better appearance. The spring-corn promised well, especially on dry foils; the strong foils being chilled by the frequent rains. The rye was in ear on the 8th, and in bloom on the 20th, when the wheat was not yet in ear. The barley was in ear on the 14th.

The pastures promised but a scanty crop of grafs, of which a coarse strong fort had taken much the ascendant; the finer having been checked or destroyed by the inclemency of the weather. The up-land pastures, or those which had not been watered, promifed the best.

The cold and too much rain did great damage to the vines, and made them shoot forked. Many plants of them which were thought to have been killed, began to make shoots. The small vineyards fared better than the large.

The fruit was well fet, and promifed plenty, though the frequent cold rains made much of it fall off the trees, and caterpillars did here and there confiderable damage: above all, the fly hurt the peaches in particular. In fome places, a fouth-wind did great damage to the apple-bloffoms.

The young pigs were trained up for fattening; and during the whole month clover was cut and carried to fodder the cattle.

The cold feason did great injury to the bees, infomuch that there was not one swarm this month, and we were obliged even to feed the weakest hives.

The hemp and flax were fine in some

places, though not in those where the hail had fallen.

The whooping cough was frequent in the beginning of this month; as were also coughs, hoarseness, and oppression on the breast; and the disorder on the lungs of cattle had not ceased.

JUNE.

THIS month was as variable as the preceding, the weather being for the most part cold and rainy. There were but few fair days. The depth of rain amounted to 4 inches 5, and fnow fell even on the lower mountains. The North wind prevailed in fome places, and in others the West.

The winter corn continued very thin, and was full of weeds. The spring corn, on the contrary, looked pretty well. Barley began to be reaped on the 23d.

Pastures, especially the wet ones, yielded but little hay, and that could scarcely be made on account of the constant rains. The lower meadows were damaged by the overflowing of the rivers, which also obstructed the making of hay and getting of it in.

The cold feafon likewise threw the vines back very much. The dressing of the vine-yards was finished with the month. Their first bloom appeared on the 14th and 15th, and it was not gone off at the end of the month, owing to the very cold season. The very high winds broke off many of their branches.

The cold and wet feafon continued to incommode the cows.

It was equally unfavourable to the bees, though they swarmed during the whole of this month.

The fruit fell off the trees in great quantities, and thereby disappointed our hopes of plenty. The slax and hemp were in great beauty.

Frequent aches were felt every where, and fome dogs ran mad.

JULY.

HE weather continued very changeable, cold, and wet, during this month. The depth of rain was 6 inches ‡. The wind generally West. The rivers overflowed in most places, and did great damage to the hay. In the night of the 10th an aurora borealis appeared, and lasted till late.

On the 10th we began to reap our winter barley, which was rather thin, but the ears were very fine. The winter and spring wheat answered pretty well; though the former was much laid by the continual rains, which likewise rendered it smutty in some places. Harvest continued from the middle to the end of this month, and in some places till pretty far in the next.

On the 8th was gathered the rape-feed, of which there was not above half a crop, owing to the coldness of the winter, and to it's bloom having been destroyed.

The lower meadows fuffered exceedingly by their being in general overflowed till the end of this month, fo that scarce any hay could be made on them, and the little that was made was extremely damaged. On the contrary the aftermath, especially on the higher grounds, was very good.

The feafon still continued unfavourable to

APPENDIX.

the vines. Their bloom did not go off till towards the middle of this month, and the grapes were few and very unequal. A few warm days at the end of the month swelled them considerably.

The flax and hemp grew very unequally, and were very full of weeds. They were both plucked about St. James's-day.

AUGUST.

HROUGHOUT the whole of this month, the weather was extremely fair and dry. We had not any where above half an inch of rain, and the wind was generally north, which contributed much to the drying of the earth. There was thunder on the 29th, when the lightening burnt a house.

The dry feafon favoured the harvesting of oats, which yielded a plentiful crop. The spring wheat ran more into straw than corn, and a too sudden ripening prevented it's plumping. The wheat and messin yielded but little when threshed, and likewise at the mill.

It was not till this month that the hay in the lower meadows could be made. The grass was coarse, dirty, and rotted in many places; and the aftermaths turned out poorly, having been burnt up by the excessive drought.

. The grapes were almost seen to grow in the beginning of this month; but the heat and drought stopt their progress, and burnt them up. What fruit remained fell off through the drought, and all the walnut, chesnut, and acorn kind, were stinted and looked poorly.

For want of grass and water, the cows lost all their milk.

The garden plants, all burnt up and destroyed by vermin, were truly piteous to behold.

The whooping cough was frequent among children, and dysenteries broke out in many places.

SEPTEMBER.

HIS month continued very fair, the wind being chiefly North. Hoarfrosts appeared about the middle of the

124 APPENDIX.

month. On the 8th there was a suffocating fouth wind.

A rain which fell in the beginning of the month prepared the earth excellently well for the feed time, and rendered it much easier to plow, which had been greatly hindered by the drought. The feed fown after this rain rose very well. The whole of the rain was an inch and a quarter.

The aftermath continued poor in some places and was plentiful in others.

The grapes ripened fuddenly, continued fmall and little in quantity, the heat having made many fall off.

The gardens and fruit continued in their perishing state.

The bees yielded little honey.

Besides the whooping cough, the small-pox seized the children, dysenteries continued here and there, and carried off more children than grown persons. Many peasants cured themselves of this last disorder, by taking an infusion of rue in milk in which some kidney suet was melted.

OCTOBER.

HE weather continued very fine during this month. More rain fell in the first half of it, than in the last. The quantity of it, in all, was 5 \(\frac{1}{2}\) inches. The nights became colder, and the hoar-frosts increased. The night of the 31st was remarkable for a violent storm of wind with a great fall of rain.

The feed time continued to the beginning of this month. The last sown feed came up very well. The crop of buck-wheat was but poor. There were but few potatoes on dry situations, occasioned by the drought.

A fecond crop of hay was cut in some places till the middle of this month. The pastures in general had recovered, and yielded plenty of food, which, in some measure, supplied the want of fodder.

The vintage began on the 13th. But very little wine was made. The apples for cyder were gathered in the beginning of this month,

The bees were in good condition, and their hives heavy.

The dysentery continued, but without blood.

NOVEMBER.

HIS month was also dry and fair. There was little rain (only i an inch,) but thick fogs. The wind generally N. and N.E.

Many springs were dried up.

The vineyards were dreffed.

The corn looked well every where, though rather thin in some places.

DECEMBER.

THIS month was pretty cold, and the fky mostly clouded. The continued drought rendered the waters very low.-Springs which had never been known to fail, were dried up; and many mills stood still for want of a stream to turn them.

The corn made a fine appearance.

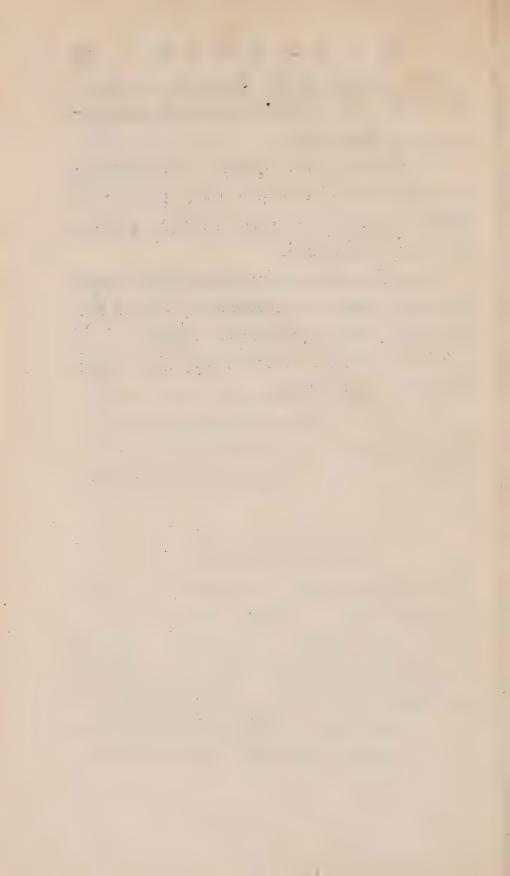

The dreffing of the vineyards was continued, till a fall of snow upon the heights put an end to that work.

The failure of the springs prevented the watering of the pastures in many places: in others the abuse of that operation proved extremely prejudicial.

From the 16th to the 21st a good deal of fnow fell upon the mountains; and on the 18th the vallies were covered with it.

The bees had so little honey, that it was necessary to feed them.

THE END.

INDEX.

Ä

A IR, the effects of, on water raised into it, page 5. Attracts water, 9. When most and when least disposed so to do, 7. is imbibed by water, 8. Dr. Halley's account of it, 9, 10.
